PROFESSIONAL GEOLOGIST CERTIFICATION

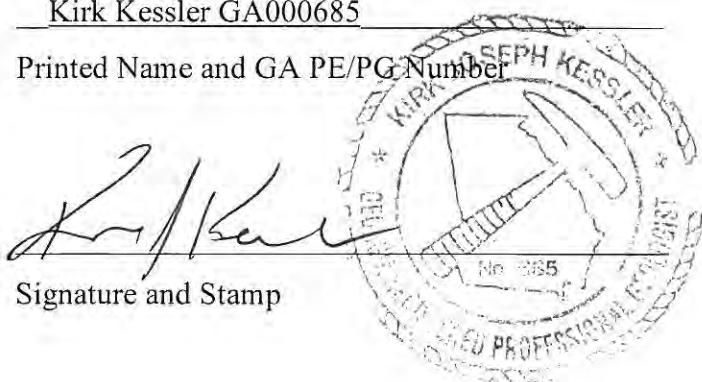

"I certify under penalty of law that this report and all attachments were prepared by me or under my direct supervision in accordance with the Voluntary Remediation Program Act (O.C.G.A. Section 12-8-101, et seq.). I am a professional engineer/professional geologist who is registered with the Georgia State Board of Registration for Professional Engineers and Land Surveyors/Georgia State Board of Registration for Professional Geologists and I have the necessary experience and am in charge of the investigation and remediation of this release of regulated substances.

Furthermore, to document my direct oversight of the Voluntary Remediation Plan development, implementation of corrective action, and long term monitoring, I have attached a monthly summary of hours invoiced and description of services provided by me to the Voluntary Remediation Program participant since the previous submittal to the Georgia Environmental Protection Division.

The information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations."

Date

1 INTRODUCTION

CEA, LLC (CEA) submitted a revised application for the Voluntary Remediation Program (VRP) (which the EPD refers to as the Voluntary Investigation and Remediation Plan, VIRP) for the Capitol USA – Dalton Facility in May 2011. In a letter dated October 3, 2011, the Georgia Environmental Protection Division (EPD) accepted CEA as a participant into the VRP. Pursuant to the conditions of the acceptance letter, this document is the first Semiannual Progress Report (Progress Report) for the Capitol Site.

The Capitol Site is located at 300 Cross Plains Boulevard, Dalton, Georgia (Site). The Site is located on a total parcel of approximately 15.31 acres. The facility is currently operated by QEP Co., Inc.

This Progress Report summarizes (by task) what actions have been taken since the VIRP was submitted (May 2011) and the upcoming activities.

2 VRP PROJECT MANAGEMENT

2.1 Financial Assurance

Per the requirements of the program, CEA provided a cost estimate and proof of financial assurance in the form of a Letter of Credit issued by First Tennessee Bank.

2.2 Professional Geologist Oversight

This Progress Report includes certification by the Professional Geologist (Kirk Kessler) specified in the VIRP. Appendix A contains a monthly summary of hours invoiced and description of services provided.

2.3 Comment Letters

Per the requirements of the EPD's acceptance letter, CEA is to respond to two comment letters from the EPD: March 31, 2011 (Comments 12-16) and October 3, 2011.

2.3.1 March 31, 2011 Comment Letter

Comment 12: Per the EPD's comment, a deep well into bedrock in close proximity to the MW-3/MW-3D is planned (see Section 3).

Comment 13: The EPD has recommended installation of a well into bedrock near MW-15 to address the concern of contamination migrating in bedrock. However, it is prudent to install the bedrock well near MW-3/MW-3D first. The results from the bedrock well at MW-3/MW-3D will be evaluated to determine whether or not it is necessary to install a bedrock well near MW-15.

Comment 14: Per the EPD's comment, a well will be installed between MW-15 and MW-16 (see Section 3).

Comment 15: Per the EPD's comment, plan-view maps specifying the concentrations of individual regulated substances in groundwater are provided in the figures associated with Section 4.

Comment 16: The EPD recommends double-casing any wells installed into bedrock and the use or rock coring during installation. These recommendations are taken into consideration for the design of the bedrock well to be placed near MW-3/MW-3D (see Section 3).

2.3.2 October 3, 2011 Comment Letter

Comment 1 concerns the identification of source material and related issues at the Site. These comments were addressed during two meetings with the EPD.

Comment 2 concerns the proposed Type 1 risk reduction standards (RRSs) for soil and groundwater. A response to each comment is as follows:

- a) Per the EPD's comments, the notification concentration (NC) value for cyclohexane in soil has been changed to 20 mg/kg, resulting in a revised Type 1 soil RRS of 20 mg/kg.
- b) Per the EPD's comment, the Type 1 groundwater and soil RRSs for cis-1,2-dichloroethene have been revised to 7 mg/kg and 0.07 mg/L, respectively.
- c) If additional constituents of concern are detected at the Site or if certification to a different RRS is desired, additional RRS values will be proposed to the EPD in a semiannual Progress Report.

The revised RRS calculations are shown in Appendix B and a summary of the revised Type 1 RRSs are presented in Table 1.

2.4 Milestone Schedule

A revised projected milestone schedule has been attached as Figure 1.

2.5 Conceptual Site Model

The Conceptual Site Model (CSM) has been updated with data collected from a recent groundwater sampling event and is included in Appendix C. Although updated with new data, the site characterization presented in the CSM and the conclusions derived from it have not changed.

3 MONITORING WELL INSTALLATION

3.1 Actions Completed

As mentioned in the VIRP, wells MW-1 and MW-1D are no longer operable and CEA plans to replace these wells. The wells were placed in the location where it was originally believed that the catastrophic spill occurred. However, as information discovered later indicated that the spill was actually located north of the AST area, the locations of MW-1 and MW-1D are not optimal for evaluating site conditions. Thus, different locations for the replacement wells have been proposed. In a recent conversations with the EPD the locations of the proposed wells have been agreed upon.

3.2 Upcoming Actions

The replacement wells will be installed according to the methodology specified in this section and at the locations shown on Figure 2.

3.2.1 Installation Plan for MW-1R

A residuum well will be installed between MW-15 and MW-16 in the area circled on Figure 2. Site constraints and high traffic areas will be considered when selecting the precise well location. The well will be of similar construction as MW-15 and MW-16. A 2-inch diameter monitoring well will be installed in accordance with *EPA Region 4 Field Branches Quality System and Technical Procedures* (SESDGUID-101-RO, February 2008).

A 2-inch diameter Schedule 40 PVC monitoring well will be installed to a depth of 25 feet inside an approximately 6-inch diameter borehole. A fifteen-foot 0.010-inch slotted screen will be used. A granular sand filter pack (appropriate for the specific screen) will be installed a minimum of 6 inches below the screen and 2 feet above the top of the screen. A bentonite pellet seal, consisting of 2 feet of dry bentonite, will be placed above the filter pack and allowed to hydrate for at least 30 minutes prior to installing the bentonite/cement grout in the well annulus, which will be pressure grouted through a tremmie pipe up to approximately 2 feet below the ground surface.

Once the annular grout has cured for a minimum of 24 hours, the well will be completed in a 12-inch diameter flush-mounted well vault within a 3-foot by 3-foot by 4-inch concrete well pad. The well will be developed at least 24 hours after the installation of the well pad in accordance with SESDGUID-101-R0. The well will be developed until it is free of visible sediment, and the pH, temperature, turbidity, and specific conductivity have stabilized.

3.2.2 Installation Plan for MW-3B

A deep bedrock well will be installed near the MW-3/MW-3D well pair. A 2-inch diameter monitoring well will be installed in accordance with EPA Region 4 *Field Branches Quality System and Technical Procedures* (SESDGUID-101-RO, February 2008). Air rotary drilling techniques will be utilized. The well screen will be set in bedrock. The actual depth will be determined during installation.

The well will be triple cased to prevent contaminant migration into the bedrock. An approximately 14-inch outside diameter (OD) bit will be advanced through the overlying residuum soils and a minimum of 1-foot into weathered shale. An 10-inch inside diameter (ID) PVC outer casing will be installed through the augers and grouted in place by pressure grouting a cement/bentonite grout through a tremmie pipe and grout shoe attached to the base of the outer casing. The annulus will be grouted up to just below the ground surface. The grout will be allowed to cure prior to advancing the borehole.

An approximately 10-inch outside diameter (OD) bit will be advanced through the weathered shale and three to five feet into competent bedrock. A 6-inch inside diameter (ID) PVC outer casing will be installed through the augers and grouted in place by pressure grouting a cement/bentonite grout through a tremmie pipe and grout shoe attached to the base of the outer casing. The annulus will be grouted up to just below the ground surface. The grout will be allowed to cure prior to advancing the borehole into bedrock.

An approximately 6-inch OD bit will be advanced through the grout plug at the base of the inner casing to approximately 20 feet below the bedrock interface, ensuring that the top of the screened interval is at least as deep as the bottom of the outer casing.

Prior to installing the well, packer testing will be conducted to ensure the screened interval is water bearing. The bottom 10 feet of the borehole will be segregated, and a pump test will be performed to determine the recharge rate, if any. If this section has sufficient recharge, the screened interval will be placed here. If this section does not have sufficient recharge, the packer system will be raised 10 feet, and the pump test will be performed again. If none of the drilled bedrock has sufficient recharge, the boring will be drilled deeper and the pump testing will continue.

Once the interval to be screened has been determined, the boring will be completed with a 2-inch diameter Schedule 40 PVC monitoring well extending above the ground surface. The screen will be between 5 and 15 feet (to be determined during installation) and the preferred screen configuration is number 20 continuous-slot screen. The bottom of the well (below the screen) will be completed with a sump that is at least 3 to 6-feet long. Two centralizers will be installed: one at the bottom sump and the other above the top of the screen. A granular sand filter pack (appropriate for the specific screen) will be installed a minimum of 6 inches below the screen and 2 feet above the top of the screen. A bentonite pellet seal, consisting of 2 feet of dry bentonite, will be placed above the filter pack and allowed to hydrate for at least 30 minutes prior to installing the bentonite/cement grout in the well annulus, which will be pressure grouted through a tremmie pipe up to approximately 2 feet below the ground surface.

Once the annular grout has cured for a minimum of 24 hours, the well will be completed in a 12-inch diameter flush-mounted well vault within a 3-foot by 3-foot by 4-inch concrete well pad. The well will be developed at least 24 hours after the installation of the well pad in accordance with SESDGUID-101-R0. The well will be developed until it is free of visible sediment, and the pH, temperature, turbidity, and specific conductivity have stabilized.

4 SEMIANNUAL GROUNDWATER SAMPLING

4.1 Actions Completed

The VIRP specifies that semiannual groundwater sampling will be conducted for a period of at least two years. The groundwater monitoring program consists of

- Annual monitoring
 - Of all wells for volatile organic compounds (VOCs)
 - Of specific wells (MW-3, MW-3D, MW-4, and MW-5) for monitored natural attenuation (MNA) parameters
- Semi-annual monitoring (in between “annual monitoring” events)
 - Of specific wells (MW-3, MW-3D, MW-4, MW-5, MW-15, MW-1R and MW-16) for VOCs

In February 2012, the first groundwater sampling event was conducted. This “annual” event consisted of monitoring all wells for VOCs and specific wells for MNA parameters.

4.1.1 Water Level Measurements

Prior to purging the wells, the depth to water was determined for each well. Groundwater elevations were calculated and are shown on Table 2 and Figure 3 along with the general direction of groundwater flow, which is to the northeast. During this sampling event, the water table intersected the ground surface in nine wells: MW-2, MW-2D, MW-4, MW-5, MW-7, MW-8, MW-9, MW-14, and MW-15. This indicates that there is not an unsaturated zone in this area. Although the groundwater table is at or above the ground surface, there is no or minimal pooling of groundwater at the surface. Table 2 displays the depth to groundwater measurements from 2011 and 2012. See the Conceptual Site Model (Appendix C) for more information about the water table conditions observed at the Site.

4.1.2 Methods

Well purging was accomplished by low-stress purging techniques using a peristaltic pump with Teflon tubing. All downhole equipment was decontaminated prior to the initiation of sampling and after each use before being used at the next sampling location. All decontamination liquids were managed by containerization. Containers were labeled and stored on-Site until disposal arrangements are finalized and the containers properly disposed.

During the sampling episode, sample tubing was slowly lowered into the well and positioned near the middle of the screened interval for all wells, and at least 2 feet above the bottom of the well (to minimize potential disturbance and re-suspension of sediment). Target pump rates were

less than the recharge rate of the well, which was verified throughout purging by periodically gauging the water level. If a drop in water level was noted during purging, the purge rate was adjusted downward to achieve water level stabilization (target drawdown of 0.3 feet or less). Wells were initially purged at a maximum initial rate of 500 milliliters per minute (ml/min), after which adjustments were made based on the drawdown response. If the target drawdown of 0.3 feet or less could not be maintained at low-flow rates, the flow rate was maintained at the lowest achievable rate less than 500 ml/min (100 mL/min, or lower if achievable).

Water quality parameters of pH, temperature, turbidity and conductivity were measured throughout the purging using a Horiba U-53 Water Quality Monitor equipped with a flow-through cell. Purging was considered complete and sampling commenced when the indicator parameters met the following criteria for three consecutive readings:

- pH measurements remained stable within 0.1 Standard Units;
- Specific conductivity varied by no more than 10%;
- Temperature was stable; and
- Turbidity varied no more than 10%, or a constant non-turbid discharge (less than 10 NTUs) was achieved.

In accordance with the U.S. Environmental Protection Agency Region IV Science and Ecosystem Support Division (SESD) Field Branches Quality System and Technical Procedures guidelines (November 2007), groundwater samples were collected using the straw method. The straw method consists of filling the tubing with groundwater using the peristaltic pump then quickly removed from the pump, and a gloved thumb was placed on the tubing to stop the water from draining out. The tubing was then removed from the well and the water was allowed to gravity-drain into sample containers.

Sample containers were provided by the analytical laboratory. Groundwater samples for VOCs analysis were collected in 40-mL glass vials preserved with hydrochloric acid with zero head space, and were prepared and labeled prior to sample collection. The containers for VOC and MNA analysis were placed in a cooler, at 4 C, and maintained under Chain-of-Custody until delivery to the analytical laboratory (Analytical Environmental Services, Inc. of Atlanta, Georgia) for the following analyses: volatile organic compounds (VOC, SW8260B); total organic carbon (SW9606A); sulfide (SW9030B/9034); chloride, nitrate, nitrite, and sulfate (SW9056A); total alkalinity (E310.2); and ethylene and methane (SOP-RSK175).

4.1.3 Results

In February 2012, samples from the eighteen wells at the Site were collected and analyzed for VOCs using Method 8260B. Samples collected from select wells (MW-3, MW-3D, MW-4, and MW-5) were analyzed for MNA parameters (total organic carbon, sulfide, chloride, nitrate, nitrite, sulfate, alkalinity, ethylene and methane). The laboratory data reports are presented in Appendix D.

4.1.3.1 VOC Results

A complete copy of the February 2012 analytical testing results is provided in Appendix D and the results of the detected constituents (along with historical results) are summarized in Table 3. Values that exceed the Type 1 RRS are highlighted in yellow.

Groundwater concentrations of total chlorinated ethenes (tetrachloroethene [PCE], trichloroethene [TCE], cis-1,2-dichloroethene [DCE], and vinyl chloride [VC]) from the February 2012 sampling event are shown in Figure 4. Similarly, groundwater concentrations of total chlorinated ethanes (1,1,1-Trichloroethane [TCA], 1,1-dichloroethane [DCA], and chloroethane [CA]) are shown in Figure 5. Isoconcentration lines are also shown on these figures indicating that the groundwater exhibits the highest concentrations immediately north of the tanker truck spill area and the plume extends north and northeast of the basin consistent with groundwater flow.

Figures showing the analytical results for individual constituents are included in Appendix E. Constituents in this Appendix include the chlorinated ethenes, chlorinated ethanes, and other constituents that had at least one result that exceeded its Type 1 RRS. These figures demonstrate that the plume has been characterized and delineated horizontally with MW-16 to the north, MW-14 to the east, MW-8 to the south and MW-17 to the west. Vertical delineation has not been demonstrated yet.

The results from the recent groundwater sampling event are generally consistent with the previous sampling events. The constituents detected, the magnitude of the constituents and the size and location of the plume are generally the same as in previous events, indicating a plume that is a steady-state.

4.1.3.2 MNA Parameter Results

MNA parameters were analyzed in samples collected from MW-3, MW-3D, MW-4, and MW-5. The following parameters were analyzed by AES for each of these wells: alkalinity, methane, ethene, chloride, nitrate, nitrite, sulfate, sulfide, and total organic carbon. These laboratory data sheets are presented in Appendix D. Parameters measured in the field during sample collection by EPS included: dissolved oxygen, temperature, pH and Redox potential (ORP), and can be seen in Appendix D. The MNA parameter results are presented in Table 4 along with the concentrations of daughter products. Based on the February 2012 data, the wells within the plume show evidence that reductive dechlorination is occurring.

4.1.4 Groundwater Modelling

Groundwater computer models using BIOCHLOR were developed and presented in the VIRP. In an effort to conservatively model site conditions, the models were calibrated using the empirical data collected from 2004 through 2007, prior to the EHC® injections. Therefore, the models assume that there is no impact from the injections. The models predict estimated concentrations that are higher than seen in empirical data collected after the injections. Thus, the models conservatively estimate future concentrations.

The groundwater models were run for the year 2012 while plotting the results from the February 2012 sampling event. The results for the chlorinated ethane and chlorinated ethene models for 2012 are shown in Figure 6 and 7, respectively. The comparison of the analytical data to the modeling results in 2012 is similar to the 2010 results. Thus, it does not appear necessary to alter the model at this point. The model continues to overestimate the concentrations of the constituents, providing a conservative assessment of future conditions.

4.2 Upcoming Actions

The next groundwater sampling event will be a semi-annual event where samples collected from specific wells (MW-3, MW-3D, MW-4, MW-5, MW-15, and MW-16) are analyzed for VOCs. This sampling event will be conducted during the third quarter of 2012. The new monitoring wells should be installed prior to this sampling event. As such, the two new wells (MW-1R and MW-3B) will be sampled for VOC analysis during the sampling event. It is anticipated that vertical delineation will be demonstrated using the results from the deep bedrock well MW-3B.

5 SOURCE AREA EVALUATION

5.1 Actions Completed

Two meetings have been held with the EPD to discuss the comments that the EPD made concerning source material in the October 3, 2011 letter. Specifically, conversations were had concerning how to define source material, potential remediation options, and the impact of paved areas. CEA is considering the EPD's position and working toward developing a response that will satisfy the EPD's concerns.

5.2 Upcoming Actions

CEA will continue to evaluate the source material issue and will submit a remedial action plan to the EPD in a future Progress Report.

6 HUMAN HEALTH RISK EVALUATION

6.1 Vapor Intrusion

The VIRP stated that the applicability of vapor intrusion modeling for industrial workers would be evaluated in the context of an operating facility (where Occupational Safety and Health Administration [OSHA] worker safety programs may govern). After a detailed review of the situation, it has been determined that OSHA regulations take precedence in evaluating any worker safety issues that may arise due to the possibility of vapor intrusion. EPA's draft *Subsurface Vapor Intrusion Guidance* (EPA, 2002) states that "OSHA and EPA have agreed that OSHA generally will take the lead role in addressing occupational exposures....In general, therefore, EPA does not expect this guidance be used for settings that are primarily occupational." OSHA has the sole jurisdiction over regulating indoor air in the workplace. OSHA has developed and enforces standards that are protective of worker health. Additionally, as many of the constituents found in the groundwater are also used in the facility, it would be infeasible to differentiate between the sources; however, it is reasonable to assume that the concentrations due to vapor intrusion would be minimal compared to the exposure due to the use of chemicals during the manufacturing processes. Notwithstanding the foregoing, CEA will develop a site-specific vapor intrusion model to evaluate the potential risk to industrial workers due to vapor intrusion.

6.2 Upcoming Actions

As discussed above, a site-specific vapor intrusion model will be developed to evaluate the potential risk to industrial workers. The results will be presented in a future Progress Report. Additionally, per the VIRP, the following potential risk scenarios will be evaluated in a future Progress Report:

- Industrial workers exposure to groundwater at the surface.
- Construction and utility workers exposure to physical contact with groundwater, vadose zone soils and/or the solid aquifer matrix.

Notes:

Physical/Chemical Parameters are from the May 2011 RSL Table unless otherwise noted.

$$\frac{(LS \times V \times DH)}{A} \times \frac{(\pi \times \alpha \times T)^{1/2}}{(2 \times D_{ai} \times E \times K_{as} \times 10^{-3} \text{ kg/g})}$$

$$LS = 45 \text{ m}$$

$$V = 2.25 \text{ m/s}$$

$$DH = 2 \text{ m}$$

$$A = 20300000 \text{ cm}^2$$

$$\pi = 3.14$$

$$\alpha = \frac{(D_{ai} \times E)}{E + \rho_s(1-E)/K_{as}} \text{ cm}^2/\text{s}$$

$$D_{ai} = D_i \times E^{0.33} \text{ cm}^2/\text{s}$$

$$D_i = \text{Chemical specific molecular diffusivity (cm}^2/\text{s)}$$

$$E = 0.35$$

$$\rho_s = 2.65 \text{ g/m}^3$$

$$Kas = (H/Kd) \times 41$$

$$H = \text{Chemical specific Henry's law constant (atm}\cdot\text{m}^3/\text{mol)}$$

$$Kd = Koc \times OC$$

$$Koc = \text{Chemical specific soil-water partition coefficient}$$

$$OC = 0.02$$

$$\text{length of side of contaminated area}$$

$$\text{wind speed in mixing zone}$$

$$\text{diffusion height}$$

$$\text{area of contamination}$$

$$\text{exposure interval}$$

APPENDIX C

CONCEPTUAL SITE MODEL

C. CONCEPTUAL SITE MODEL

The CSM is intended to establish a common knowledge base about the Property and its environmental condition, to facilitate the development of basic remedial action objectives appropriate for the Property, and to allow an informed decision regarding possible remedial action measures for the Property. This section describes the surface and subsurface features at the Property, discusses the fate and transport of chlorinated solvents, and discusses the potential receptors and exposure pathways associated with the Property.

C.1 Elements of the Conceptual Site Model

The figures attached to this section and the Progress Report are plan view and profile diagrams depicting the extent of chlorinated solvents in the subsurface. Viewed in total, these figures give a three-dimensional representation of the site conditions.

C.2 Ground Surface Features

The Property consists of one steel frame building (approximately 100,000 sf) with concrete masonry walls and slab on grade concrete floor with a metal roof. Parking lots are located to the north and east of the building and a gravel road/driveway runs along the eastern and southern sides of the building. Ten loading docks are located on the east wall of the facility and several lean-to structures are on the south and west sides. There is limited grassy terrain on the eastern and northern side of the Property. The topography of the Property gently slopes from the south to northeast. A shallow drainage ditch is located around the southern and eastern side of the Property and conveys runoff toward Cross Plains Boulevard. Samples collected from the southern drainage ditch did not contain concentrations of VOCs above HSRA Notification Concentrations (WRS, 2006). A subgrade storm drain system runs from the southeastern side of the building, across the spill area and then north to the ditch along Cross Plains Boulevard. There are no surface water features on or adjacent to the Property. A topographic map is provided in Figure 1 and the site features are shown on Figure 2.

C.3 Source of Contamination

In January 1995, a documented release of approximately 585 gallons of reclaimed 1,1,1-trichloroethane (TCA) occurred from a delivery truck due to failure of the tanker sidewall. Figure 2 depicts the approximate location of the spill¹. Spill response involved containment of the spill area with dikes and product was recovered using a vac truck. Post spill response involved excavation of surface soils at the spill site and off-site disposal². Groundwater samples

¹ The location depicted for the tanker truck spill has been modified from previous depictions in the Corrective Action Plan Addendum (EPS, 2009) due to recently-discovered information.

² There is no documentation of the dimensions or specific locations of the soil excavation.

were not collected during the post spill response. However, an Environmental Investigation (Tri-State, 2004a) in August 2004, identified TCE, PCE, and daughter products in the subsurface and groundwater samples. This spill is the likely source of TCA and the daughter products detected in the groundwater. The spill is also the likely source of PCE/TCE and daughter products detected in the groundwater, as the reclaimed TCA likely contained PCE/TCE.

The ASTs near the tanker spill location are currently being used to store solvents for use in the facility's processes. The secondary containment appears in good condition.

C.4 Subsurface Features

C.4.1 Geological Setting

The Property occurs within the Valley and Ridge Physiographic Province of northwest Georgia. The province is dominated by a northward-trending valleys separated by low, rounded ridges and by high, steep-sided ridges (Cressler, 1974). The stratigraphic units below the Property are within the Conasauga Formation of the middle and late Cambrian system, which is underlain by the Rome Formation. Cressler (1974) describes the Conasauga Formation as follows:

Thickness: 3,000-5,000 feet (maximum thickness unknown)

Lithology: The formation consists of alternating units of shale and limestone that vary in thickness and relative proportion from place to place. In some areas the formation is mainly shale.

The lithology seen at the Property is mainly shale. The middle unit of the Conasauga Formation is composed of approximately 1,000 feet of light green and yellowish clay shale containing small lenses of blue limestone. Some silty shale is also present, but in smaller quantities than in the lower unit.

A cross section location map is included as Figure 3, and cross sections are shown on Figures 4 and 5. As depicted on these figures, the shallow stratigraphic profile at the Property consists of 4 to 6 feet of fill material placed during construction of the facility, followed by 10 to 15 feet of unconsolidated soil (clayey sand or sandy clay or shaley clay, but predominantly sandy clay) grading to weathered shale approximately to 15 to 20 feet bgs.

C.4.2 Hydrogeological Setting

Cressler (1974) describes the hydrologic properties of the Conasauga Formation as follows:

Wells in shale yield up to 5 gpm, or in some locations 17 gpm; and dry wells also occur. Wells in limestone normally supply between 5 and 25 gpm and ones properly located with respect to the drainage will furnish up to 300 gpm. Most wells are less than 300 feet deep, though some extend to a depth of 500 feet. Wells penetrating shale and limestone mixed generally supply from about 2 to 20 gpm, but some yield up to 100 gpm if they are near a source of recharge. The well water varies from soft to hard and has a low to moderate iron content. Some large springs have openings in the Conasauga, but discharge water from the Knox Group.

The water table at the Property fluctuates on the scale of 5-8 ft at a given location, with many locations exhibiting a high water table mark at the ground surface. Although the water table

intersects the ground surface, the conditions are such that there is no or minimal pooling of water on the ground surface. In the spring of 2011 a weekly groundwater measurement program was implemented for three consecutive weeks to better define the high water table conditions. Depth to groundwater measurements were made at all the existing wells at the Property on three consecutive weekly site visits. The results are presented in Table 2 of the Progress Report along with the results from the February 2012 sampling event. This information was combined with the historical groundwater measurements to determine the historical high water table elevations, which can be seen on the cross-sections (Figures 4 and 5). The table below shows the high water table mark for the shallow wells. Ten of the shallow wells have exhibited conditions where the groundwater table intersects the ground surface. The only wells that have consistently shown groundwater deeper than two feet below the ground surface are MW-6, MW-11, MW-12 and MW-13. Figure 6 shows the locations of the wells and their high water table marks. Figure 3 of the Progress Report is a potentiometric surface map from the February, 2012 gauging event. The overall groundwater flow direction is to the northeast.

Well	High Water Table Mark: Depth Below Ground Surface (ft)

MW-14	0
MW-15	0
MW-16	0.67
MW-17	0.72*

* Ground surface elevation unknown, depth below top of casing shown

The topographic map (Figure 1) is dated 1982, prior to the construction of the facility. This map shows that the facility is located in a low topographic relief (valley) area. This figure (which

shows the approximate location of the facility) also shows that an intermittent stream ran through where the southeastern corner of the building now stands. This stream ran in a northeasterly direction across where the Property now exists. This is the same direction as the groundwater flow seen currently at the site (Figure 3 of the Progress Report). As mentioned previously, there is 4 to 6 feet of fill material that was placed in this low topographic area during construction of the facility. The high water table conditions are likely occurring because the valley bottom was filled with material having higher permeability than the native soil. Additionally, the valley bottom pitches from the south to the north creating artesian pressure when the water table is generally high.

Figure 6 was used to define soil zones on the Property based on the high water table marks. The fully saturated zone is the area where the subsurface is fully saturated due to the water table intersecting the ground surface. The fully saturated zone shown on Figure 6 was conservatively assumed to be the area between the wells where the groundwater table intersects the ground surface. It is very likely that the actual fully saturated zone is larger than this area. In the fully saturated zone there is no vadose zone. The approximate depth of the vadose zone in other areas of the site shown on Figure 6 are based on the depth to groundwater measurements. It is reasonable to infer that the fully saturated zone is located where the intermittent stream formerly ran.

As mentioned above, in the fully saturated zone there is no vadose zone soil. Instead, there is a solid aquifer matrix that will be evaluated to determine if there is potential source material. In the other zones there is a vadose zone soil matrix above the high water table mark and solid aquifer matrix below the high water table mark.

Hydraulic gradients, hydraulic conductivity and transmissivity calculations³ were presented in the CAP (WRS, 2006). Horizontal hydraulic gradients range from 0.0083 to 0.0125 feet/foot. The hydraulic conductivity ranges from 2.63 to 8.09 feet per day with an average and geometric mean of 5.29 and 4.46 ft/day. The transmissivity ranges from 244.61 to 1,452 gallons per day per foot (gpd/ft). Ranges of groundwater flow velocities were estimated using the modified Darcy equation:

$$V = Ki/n_e$$

where:
V = average linear velocity
K = hydraulic conductivity
i = hydraulic gradient
 n_e = effective porosity

Groundwater flow velocities were estimated using the average hydraulic conductivity 5.29 ft/day and an estimated effective porosity (n_e) for site soils of 0.3. Using the range of hydraulic gradients (0.0083 to 0.0125 feet/ft), the range of groundwater flow velocities were calculated to be approximately 53 to 80 ft/year.

³ Hydraulic conductivity and transmissivity were determined by slug tests on four monitoring wells using the Bouwer and Rice method.

C.5 Extent of Contamination

As mentioned previously, three different matrices are of interest at this Property: groundwater, vadose zone soil, and the solid aquifer matrix. The extent of contamination in each of these matrices is discussed in this section.

C.5.1 Groundwater Conditions

Twenty groundwater monitoring wells at the Property have been sampled over time (boring logs and well construction diagrams are presented in Appendix F and Appendix G of the VIRP, respectively). Additionally, nine direct push-point water samples were collected in March 2009. A summary of the historical analytical results for constituents detected in the recent sampling event is presented in Table 3 of the Progress Report.

TCA, PCE, and TCE are the primary constituents of interest at the Property due to the known TCA spill and because these constituents (and daughter products) have been consistently detected above RRSs. These chlorinated solvents can degrade biologically in the subsurface. Through reductive dechlorination, parent compounds (i.e., TCA and PCE/TCE) can be degraded biologically into daughter products. TCA can be degraded into 1,1-dichloroethane (DCA) and then chloroethane (CA). Similarly, PCE can be degraded into TCE, cis-1,2-dichloroethene (DCE) and vinyl chloride (VC). Groundwater concentrations of total chlorinated ethanes (TCA, DCA and CA) in 2012 are shown in Figure 5 of the Progress Report. Similarly, groundwater concentrations of chlorinated ethenes (PCE, TCE, DCE and VC) are shown in Figure 4. The spatial distribution of constituents in groundwater is consistent with the pattern observed in the subsurface solid matrix with groundwater exhibiting the highest concentrations immediately north of the tanker truck spill area. The primarily direction of the groundwater plumes are to north and northeast of the basin consistent with groundwater flow.

The distribution of parent compounds and degradation products demonstrate degradation has occurred over the Property's history, with degradation products having a tendency to exhibit a greater spatial distribution compared to the parent compounds. Degradation products also tend to exhibit higher concentrations down gradient from the tanker truck spill area compared to the source area at the tanker truck spill area.

Figures 7 and 8 show time series graphs for monitoring well MW-5 (which is in the plume, downgradient from the tanker truck spill area) for the PCE and TCA degradation parameters, respectively. These figures demonstrate that biodegradation is occurring in the plume. The figures clearly show that the peak for the parent compounds (TCE and TCA) appears first followed by the next degradation parameters (DCE and DCA) then the final degradation parameters (VC and CA). (There were only very small concentrations of PCE, likely due to biodegradation occurring prior to reaching MW-5.)

The plume has been characterized and delineated horizontally (see Figures 4 and 5 in the Progress Report) with MW-16 to the north, MW-14 to the east, MW-8 to the south and MW-17 to the west. Three pairs of monitoring wells are available to evaluate the vertical extent of VOCs (MW-1/MW-1D, MW-2/MW-2D, and MW-3/MW-3D). However, MW-1 and MW-1D have been damaged and are no longer operable. A review of data from the MW-2 and MW-3 well

clusters identified VOCs in both the shallow and deep wells, but both the number of constituents and concentrations are lower in the deep well of each pair. Thus, the concentrations of constituents decrease with depth. However, MW-2D and MW-3D are not much deeper than MW-2 and MW-3 and are all in weathered shale. The well depth for MW-2 is 15 ft bgs and 17.3 ft bgs for MW-2D. Similarly, MW-3's well depth is 15 ft bgs and MW-3D's is 22.5 ft bgs. As there are no wells located deeper than MW-3D, vertical delineation has not been completed yet. It is anticipated that vertical delineation will be completed with results collected after the installation of a bedrock well near MW-3/MW-3D.

C.5.2 Solid Aquifer Matrix and Vadose Zone Soil

C.1.1.1 Subsurface Investigations and Matrix Classification

Although the solid aquifer matrix and vadose zone soil will be considered separately in terms of potential corrective action, for ease of presentation and delineation both matrices will be discussed together. Six subsurface investigations have been completed to date at the Property. A brief summary of the historical investigations is provided below. Solid-matrix samples were collected and analyzed for VOCs during these investigations both from the zone of the water table fluctuation and from beneath the low water table mark, for the purpose of helping to describe/define the groundwater conditions from a perspective of source area(s) that might warrant a different remedial action approach to that for the dissolved-phase plume. A summary of the analytical results is presented in Table 1 and the sample locations are shown on Figure 9. Available boring logs are presented in Appendix F of the VIRP.

Figure 9 also shows the high water table zones. This figure was used to classify each sample collected as either vadose zone soil or being in the solid aquifer matrix by determining whether the sample collected was above or below the estimated high water table mark at that location and depth. Thus, Table 1 indicates whether each sample is in the solid aquifer matrix or vadose zone soil.

July 2004 Subsurface Investigation. In July 2004, four solid matrix samples were collected during the installation of MW-1D, MW-2D, MW-3 and MW-3D. Sample collection depth ranged from 8 to 15 ft bgs. Chlorinated ethenes, ethanes and a single detection of toluene (at MW-2D) were detected in these solid matrix samples. Note that the high water table mark for these wells is less than 1 ft bgs (with all but MW-3D having a groundwater level at the ground surface), indicating that all of these solid matrix samples were collected from below the high water table mark.

August 2005 Subsurface Investigation. In August 2005, 13 solid matrix samples were collected from direct-push cores to the east of the main facility building (identified as the GP samples in Figure 9). Samples were collected at depths from 2 to 8 ft bgs. The only sample locations that are in the greater than 2 ft high water table zone are GP007 and GP008. These two samples will be considered as representing the vadose zone while the remaining samples are in the solid aquifer matrix. Consistent with the July 2004 investigation, chlorinated ethenes and ethanes were detected in these samples.

June 2006 Subsurface Investigation. In June and July 2006, nine solid matrix samples were collected during the installation of additional site monitoring wells (MW-8 to MW-16 in

Figure 9). Samples were collected at depths from 5 to 15 ft bgs. The high water table mark for all of these locations is less than 5 feet, thus all of these samples are in the solid aquifer matrix. Only two sample locations exhibited chlorinated ethenes (MW-10 and MW-11) and one location exhibited compounds characteristic of petroleum hydrocarbons or BTEX compounds (MW-15).

MIP Profiling and Associated Core Sampling. Subsurface investigations were performed in October, 2008 to delineate conditions beneath the AST containment basin, beneath the nearby facility structure and areas hydraulically downgradient. These investigations were completed with a combination of both traditional direct-push core sampling and membrane interface probe (MIP) profiling. The MIP profiling, unlike tradition core sampling, yields nearly continuous measurements of total VOCs in the subsurface as it is advanced, providing a more continuous screening-level characterization of the subsurface conditions. Appendix I of the VIRP contains excerpts of the MIP data originally provided in the *Source Area Investigation Report* (EPS, 2008). Interpretation of the MIP profiles indicate that residual VOC product (if present) is entrained in the upper surficial deposits and has not been released in sufficient quantities to remain mobile and transport to deep depths. The MIP profiles also suggest the presence of a dissolved-phase plume.

After completion of the MIP field screening, six core samples were collected at offsets (1 to 2 ft) to the completed MIP borings to quantify VOCs and their respective concentrations (MIP sample series on Figure 9). Solid media samples were collected to characterize a range of electron capture detector (ECD) responses from the MIP both above and below the measured water table during this point in time. A comparison of the core sample and MIP result are presented in Appendix I of the VIRP. All but two (MIP-6 and MIP-12) of these sample locations fall in the fully saturated zone, and are, therefore, classified as being in the solid aquifer matrix. MIP-6 and MIP-12 fall in the 0-1ft high water table zone. However, all of the samples collected at these locations were at depths greater than 1 ft bgs. Therefore, these samples are also classified as being in the solid aquifer matrix.

AST and Facility Subsurface Samples. On 12 January 2009, subsurface solid matrix samples (designated as “SS” samples on Figure 9) were collected from multiple locations beneath the facility foundation slab, from beneath the AST containment basin slab, and one sample adjacent to the subgrade site storm drain. Concrete cores were removed from the facility foundation prior to the collection of direct-push cores. Samples from beneath the AST containment basin were collected by first hand-excavating a trench adjacent to the containment basin wall to allow access under the basin slab with a hand auger. A hand auger was then advanced at an angle horizontally underneath the AST containment basin slab (a few feet to the basin interior from the outer wall) to a depth of 1.5 to 2 ft. Seven of the locations (SS-BLDG-1, SS-BLDG-5, SS-BLDG-6, SS-AST-1, SS-AST-2, SS-HA-1, and SS-HA-2) sampled are within the fully saturated zones, and are thus in the solid aquifer matrix. Two of the locations (SS-BLDG-2 and SS-BLDG-4) are in the 0-1 ft high water table zone. Samples were collected at 1 ft bgs at each of these locations. Thus, these two samples are considered to be at the high water table, and, thus, are being considered vadose zone soil. However, another sample was collected below 1 ft bgs at location SS-BLDG-2 and is, thus, considered to be in the solid aquifer matrix. The remaining sample (SS-BLDG-3) is in the 1-2 ft high water table zone. The sample collected from this location was collected at 1 ft bgs and is, thus, considered a vadose zone soil.

Supplemental Subsurface and Groundwater Samples. On March 10, 2009, 10 subsurface solid matrix samples were collected from the area north of the AST containment basin and at the furthest known extent of the VOC groundwater plume. The highest concentrations were observed in SO-3, which was collect in the truck spill area, just north of the AST containment area. With the exception of SO-5, all of these sample locations are within the fully saturated zone. Therefore, the samples collected from these locations are considered to be in the solid aquifer matrix. SO-5 is in the 0-1 ft high water table zone; however, the sample collected at this location was at 5 ft bgs and is, thus, also in the solid aquifer matrix. In 2010, three soil samples were collected for estimating the permanganate natural oxidant demand. VOCs were also analyzed from one of these locations (SO-10), which was located next to the AST containment area.

C.5.2.1 Extent of Chlorinated Solvents

Figures 10 and 11 show the extent of total chlorinated ethanes and ethenes in these solid matrix samples, respectively. Where more than one sample was taken at a location, the highest total result is shown. The spatial distribution of chlorinated solvents in the solid subsurface matrix exhibits a clear concentration gradient with highest values occurring adjacent to the north end of the AST containment area (near the area where the tanker truck spill occurred). Chlorinated solvent concentrations lessen with distance from this area. This area of high concentrations is in the fully saturated zone indicating that it is comprised of the solid aquifer matrix (without any vadose zone soil). The presence of source material in the solid aquifer matrix in this area is discussed further in Section 5 of the Progress Report.

C.5.2.2 Delineation

Delineation is only appropriate for the vadose zone soils. However, because much of the area of interest on the Property does not have vadose zone soils, the solid aquifer matrix is included on the delineation figures to aid in demonstrating delineation for the vadose zone soils. Figures 10 and 11 show that the solid matrix has been delineated to background in all directions, except for MW-11 on the west side. The only constituents detected in MW-11 is trichloroethene at a concentration of 0.008 mg/kg, which is below the Type 1 RRS for trichloroethene (0.5 mg/kg). Thus, the solid matrix material has been delineated to the Type 1 RRS in all directions.

C.6 Fate and Transport Summary

C.6.1 Physical Fate and Transport

The primary parent constituents of interest at this Property are TCA, PCE, TCE and their breakdown products. In their product state, TCA, PCE and TCE are dense nonaqueous phase liquids (DNAPLs), which can be classified as either mobile or immobile. In the groundwater, they are found in a dissolved state. Thus, there are three states of interest: mobile DNAPL, immobile DNAPL and dissolved-phase. Following release at the surface, DNAPLs actively spread primarily due to gravity. Vertical migration continues through the vadose zone and aquifer until the released DNAPL either loses continuity and becomes dispersed into isolated bodies (referred to as ganglia or globules) or reaches a less permeable layer where it either accumulates in a pool or flows semi-laterally along the layer. During downward migration, a

globule trail of residual product and sorbed-phase contamination is left. The DNAPLs in this trail are incapable of further migration. Eventually, the entire DNAPL mass becomes immobile as the gravity head is lost.

When the groundwater comes in contact with a DNAPL, an aqueous phase plume is created and slowly fed by the sorbed, residual or pooled DNAPL. A residual-phase DNAPL source offers a large surface contact area (as compared to a pooled DNAPL) for contact with the groundwater, which results in a higher flux from the DNAPL state to the dissolved phase. This in turn results in an accelerated rate of DNAPL depletion. Once in the dissolved-phase, the solvents are transported in the water primarily along in the direction of the groundwater flow, but also horizontally (cross- or up-gradient) due to dispersion and diffusion. The aqueous phase plumes become elongated in the hydraulically down-gradient direction and are subject to attenuation process such as dispersion, sorption, matrix diffusion and biodegradation (discussed in the next section). All aqueous plumes will eventually reach a steady-state condition where the leading edge and side edges no longer expand. For this Property, the predominant groundwater flow is laterally downgradient (to the northeast). Additionally, the rapid rise and fall of the water table gives evidence that the groundwater provides for transport of dissolved phase chlorinated solvents to the ground surface (upward migration) through artesian flow and very shallow water table conditions. The water table fluctuation brings dissolved phase contaminants into contact with the solid matrix, resulting in the contaminant becoming entrained and sorbed in the solid matrix. Thus, the fluctuating groundwater table is another transport mechanism occurring at the Property. The groundwater could carry the solvents both horizontally and upwards toward the surface. This creates another potential exposure pathway (exposure to groundwater at the ground surface) that will be evaluated.

PCE has been measured as high as 3.9 mg/L at MW-3, which is next to the location of the spill. This concentration represents approximately 3.2% of the aqueous solubility. According to Cherry and Feenstra (1991), concentrations exceeding 1% of the compound's aqueous solubility indicates the possible presence of DNAPL. Thus, there may be a continuing flushing of PCE from the aquifer matrix near the spill site. An evaluation of the site conditions indicates that at this Property any DNAPLs have remained as a residual smearing in the upper portions of the subsurface and are not present as mobile "pools" of NAPL.

Data collected from groundwater and solid matrix samples at the Property support the lateral movement of dissolved-phase solvents by groundwater. Concentrations in the shallow solid matrix samples outside the vicinity of the AST containment area are attributable to the migration of the contaminants in the shallow fluctuating groundwater. The analytical results of the downgradient wells indicate that the plume has migrated to the northeast (in the direction of groundwater flow). The dissolved plume has been delineated in the downgradient direction and has not migrated off the Property.

C.6.2 Biological Degradation

Chlorinated solvents can also degrade biologically in the subsurface through reductive dechlorination. As mentioned previously, parent compounds (i.e., TCA and PCE) can be

degraded biologically into daughter products (DCA, CA, TCE, DCE and VC). Four lines of evidence are presented in this section to demonstrate that reductive dechlorination is occurring.

C.6.2.1 Daughter Products and Time Series Graphs

The presence of the daughter products at the Property indicates that biological degradation is occurring. Additionally, time series figures (Figures 7 and 8) show the decrease of parent products and subsequent increase in daughter products over time.

C.6.2.2 MNA Parameters and Screening Method

Other parameters can also be used to indicate that biodegradation is occurring. During the October 2010 sampling event, additional analyses were conducted to provide evidence as to whether or not reductive dechlorination is occurring at the Property. Monitored Natural Attenuation (MNA) parameters were analyzed in samples collected from MW-3, MW-3D, MW-4, MW-5 and MW-8. The following parameters were analyzed by AES for each of these wells: alkalinity, sulfide, methane/ethane/ethene, chloride, ferrous iron, nitrate, nitrite, sulfate, and total organic carbon. These laboratory data sheets are presented in Appendix H of the VIRP. Parameters measured in the field during sample collection included: dissolved oxygen, temperature, pH and Redox potential. As a part of the microbial testing conducted by Microbe Inotech Laboratories, certain MNA parameters (pH, iron, ammonia, nitrite, nitrate, orthophosphate, sulfate and total organic carbon) were also analyzed for MW-3, MW-3D, MW-4 and MW-5.

As part of the process for determining whether anaerobic biodegradation is occurring, the Environmental Protection Agency (EPA) guidance document “*Technical Protocol for Evaluating Natural Attenuation of Chlorinated Solvents in Groundwater*” (EPA, 1998) includes a scoring process using indicator parameters. Table 2 shows the results of this screening at the Property using data collected during the October 2010 sampling event. Results are shown for the primary wells within the plume (MW-3/3D, MW-4, and MW-5), two side-gradient wells (MW-12 and MW-14), and an upgradient well (MW-8) and downgradient well (MW-16). Based on the October 2010 results, the wells within the plume show strong evidence that reductive dechlorination is occurring, while the wells up-, side- or down-gradient of the plume show limited or inadequate evidence that reductive dechlorination is occurring, which is not unexpected since there are low to non-detectable concentrations of chlorinated solvents in these wells. Results of MNA testing from the February 2012 sampling event continue to show that reductive dechlorination is occurring (see Table 4 of the Progress Report).

C.6.2.3 Microbial Testing

Tables 3 and 4 show the results of microbial testing at two different laboratories. Microbe Inotech Laboratories performed the first type of testing, which was based on doing anaerobic (Table 3) and aerobic (Table 4) cultures using plate counting techniques. The laboratory data report can be found in Appendix H of the VIRP. The first column shows the density (number of colony forming units per mL) of anaerobic or aerobic organisms from each well. The next several columns show the percent of different strains of organisms that were seen in the culture from each well. After identification of the strains, an endpoint assay was conducted on each strain. The strains were individually cultured with either TCA or TCE as the carbon source. The

endpoint assay results (shown at the bottom of each table) show that the microorganisms present in MW-3D and MW-5 grow very well on TCA and TCE. Interestingly, the aerobic assay shows that the microorganisms in MW-5 also grow very well on TCA or TCE. This indicates the potential for multiple types of mechanisms to occur at the Property. This testing shows that degradation of TCA and TCE is favorable in MW-5 and to a lesser extent in MW-3D. One drawback of the plate counting technique is that it does not account for viable (live) cells and cultivation techniques can underestimate the total population.

Microbial Insights performed the second microbial testing technique, which is called CENSUS. The laboratory data report is presented in Appendix H of the VIRP. DNA is extracted from the groundwater samples and quantitative real-time polymerase chain reaction analysis is used to detect and quantify specific targets of interest (e.g., a specific microbial species). Samples from MW-3 and MW-5 were analyzed for *Dehalococcoides spp* and *Dehalobacter spp*, both of which are common dechlorinating bacteria. *Dehalococcoides spp* is the only known group of bacteria capable of completely degrading PCE to ethene. *Dehalobacter spp* is capable of dechlorinating PCE to cis-DCE and TCA to chloroethane. Thus, the presence of these species indicates that reductive dechlorination of PCE/TCE and TCA is favorable and likely occurring. The functional genes for *Dehalococcoides spp* were also analyzed to determine if the genes are present that are necessary for the different steps in the dechlorination chain. *tceA* reductase is the gene responsible for reducing TCE to DCE. Vinyl chloride reductase is the gene responsible for reducing vinyl chloride to ethene in multiple strains. Similarly, *bvcA* reductase is the gene responsible for vinyl chloride reducing to ethene, but only for a specific strain (BAV1) of *Dehalococcoides spp*. The absence of VCreductase and *bvcA* reductase would indicate that vinyl chloride would accumulate instead of further degrading to ethene. The results (Table 3) show that these organisms and genes are present in both wells, but are significantly higher in MW-5. This indicates that the conditions are favorable and most likely occurring for reductive dechlorination of PCE to ethene and TCA to chloroethane in both of these wells, but is much more likely in MW-5.

Based on these results, conditions are favorable at the Property for reductive dechlorination, especially in the direction of MW-3 to MW-5.

C.6.2.4 Modeling

Computer modeling using BIOCHLOR (see Appendix J of the VIRP) provides further evidence that reductive dechlorination is occurring. BIOCHLOR is a computer model that simulates natural attenuation of dissolved chlorinated solvents. In an effort to conservatively model site conditions, the model was calibrated using the empirical data collected from 2004 through 2007, prior to the EHC® injections. Therefore, the model assumes that there is no impact from the injections. Model simulations were conducted through 2030 to determine estimated concentrations at different wells throughout and beyond the plume. Please refer to Appendix J of the VIRP for more information. Results from the February 2012 sampling event are compared to the 2012 model results in Figures 6 and 7 of the Progress Report.

C.7 Potential Receptors and Exposure Pathways

C.7.1 Setting

The Property includes a single-story manufacturing building, parking lots located to the east and north of the building, loading docks on the east side of the building, a gravel driveway to the east and south of the building and small grassy areas on the eastern and northern portions of the Property.

The adjoining properties are used for commercial purposes or are currently vacant. Properties immediately adjacent to the Property include the Parish Towing Company to the north, the Anderson Company to the east and vacant wooded properties to the South and West. The area surrounding the Property is zoned for heavy manufacturing, with some general agricultural zoned areas beyond the manufacturing zoning.

C.7.2 Human Health

The nearest residence is greater than 2000 feet northwest of the Property. The Property and surrounding area are serviced by public drinking water system provided by Dalton Utilities. According to a representative at Dalton Utilities, all of Whitfield County is served by the utility. The closest drinking water well is located 1.125 miles from the Property. In addition, as described in the Release Notification (Tri-State, 2004b): a) groundwater flow at the Property is to the northeast and this well is to the north-northwest, b) the Property and the well are approximately at the same elevation resulting in no head difference to drive groundwater toward the well, c) based on surface water drainages the Property and the well are cross-gradient, and d) there are multiple groundwater divides between the Property and the well that would prevent groundwater migration from the Property to the well. Thus, the well is not directly downgradient of the Property and the well is located in an area where public water is available. As the Property and surrounding areas are on public water, ingestion of groundwater is not a complete exposure pathway.

The other potential exposure pathways include exposure to vadose zone soil, source material in the solid aquifer matrix, dermal contact with groundwater and vapor intrusion. The potential human receptors include an industrial worker and construction/utility worker.

C.7.2.1 Industrial Worker

As the area impacted by the release is mostly covered by concrete and/or gravel, exposure to vadose zone soil or potential source material in the solid aquifer matrix is not a complete exposure pathway for the industrial worker. However, due to the shallow depth of groundwater, potential exposure of workers to groundwater at the surface will be evaluated under the VRP program for this Property; however, there is no or minimal pooling of water at the ground surface.

Some chlorinated compounds have been detected in wells inside the manufacturing building. Thus, there is a potential for a vapor intrusion pathway. The EPD has requested that vapor intrusion modeling be conducted for the Property. However, as discussed in Section 6.1 of this

Progress Report, the evaluation of vapor intrusion is inappropriate for this Site as OSHA regulations take precedence for the protection of worker safety.

C.7.2.2 Construction and Utility Workers

The current and/or potential future human receptors are Construction and Utility Workers. No construction or utility activities are currently planned at the Property; however, it is possible that additional buildings could be constructed on the Property in the future. Construction or utility works may be exposed by physical contact with contaminated groundwater, vadose zone soils and/or the solid aquifer matrix. The potential risk to Construction or Utility Workers in physical contact with groundwater, vadose zone soils and/or source material in the solid aquifer matrix at the Property will be evaluated as a part of the VRP program.

C.7.3 Ecological

The area impacted by the release is mostly covered by concrete and/or gravel. There is continual traffic over this area and unloading operations. The area does not represent quality habitat as it lacks natural vegetative cover, structure, and diversity and is unlikely to ever have substantial vegetative cover due to ongoing maintenance activities. Disturbances from vehicles and facility operations have and will continue to disturb wildlife and cause animals to seek less frequently disturbed areas off the Property.

TEL: (404) 315-9113
FAX: (404) 315-8509

RE: Capitol Adhesives

Dear Timmerly Bullman:

Order No: 1202819

Analytical Environmental Services, Inc. received 23 samples on 2/9/2012 1:15:00 PM for the analyses presented in following report.

No problems were encountered during the analyses. Additionally, all results for the associated Quality Control samples were within EPA and/or AES established limits. Any discrepancies associated with the analyses contained herein will be noted and submitted in the form of a project Case Narrative.

AES' certifications are as follows:

- NELAC/Florida Certification number E87582 for analysis of Environmental Water, soil/hazardous waste, and Drinking Water Microbiology, effective 07/01/11-06/30/12.
- AIHA Certification ID #100671 for Industrial Hygiene samples (Organics, Inorganics), Environmental Lead (Paint, Soil, Dust Wipes, Air), and Environmental Microbiology (Fungal) effective until 09/01/13.

These results relate only to the items tested. This report may only be reproduced in full.

If you have any questions regarding these test results, please feel free to call.

A handwritten signature in black ink, appearing to read "James Forrest".

James Forrest
Project Manager

Case Narrative

Sample Receiving Nonconformance:

A Trip Blank was provided but not listed on the Chain of Custody. Trip blank analyzed at no cost to the client.

Volatiles Organic Compounds Analysis by Method 8260B:

Chloroform, Vinyl chloride, 1,1-Dichloroethane, Freon-113, 1,1,1-Trichloroethane, 1,1-Dichloroethene, 1,2-Dichloroethane, cis-1,2-Dichloroethene, Trichloroethene, & Tetrachloroethene value for sample 1202819-003A is "E" qualified indicating an estimated value over linear calibration range. Sample could not be diluted and reanalyzed due to second vial used as matrix spike/matrix spike duplicate.

1,1-Dichloroethene, & Trichloroethene values for the QC samples 1202819-003AMS/MSD are "E" qualified indicating estimated values over linear calibration range due to the level of target analyte present in the unspiked sample.

Monitoring Worksheet Sampling Form

EPS Project: Capitol Adhesives							
Well ID:	MW-16	Sampling Performed By:	Jeff Dennis / Ryan Tong	Field Conditions:	<u>45°F clear (partly cloudy)</u>		
Well Construction:	Flush mount	Well Labeled:	Well Cap: <u>15</u> Well Locked: <u>NO</u>	General Condition of Well:	<u>good</u>		
Well Depth from TOC:	<u>.05</u>	Well Diameter (in):	<u>2"</u>	Condition of surrounding area:	<u>grass</u>		
Height (Ht) of water in well (Well depth from TOC - Static level from TOC):	<u>2"</u>	Volume of water in well (Ht. x(.16 for 2")(.653 for 4")(.1469 for 6"):	<u>3.87</u>	Depth to Water from TOC:	<u>.88</u>		
Purging Method:	<u>low flow / 10 strokes</u>	Sample Method:	<u>stirring</u>	Method of measure:	<u>WLM</u>		
Time @ Start of Purge:	<u>3:47</u>	Three Well Volumes (gal):	<u>4.50</u>	Comments			
Sample Parameters:	<u>DO</u>						
Time	Volume (gal)	Temp (oC)	pH	Cond. (mS/cm)	DO (mg/L)	Turbidity (NTU)	ORP (mV)
8:45	8.5	13.94	4.74	454	0.00	11.4	192
