# EXECUTIVE SUMMARY

In 2000, Vopak Terminal Savannah, Inc. (VTSI) acquired Paktank Corporation (Paktank) that maintained a bulk liquid storage terminal on a land parcel in Savannah, Georgia leased from the Georgia Ports Authority (GPA). In 1996, Paktank notified the Georgia Environmental Protection Division (EPD) about a solvent release discovered in one of its tank farms. The release was composed of PCE and its typical degradation products. Paktank attributed the source of the release to tetracholoroethylene also known as percholoroethylene (PCE) that was stored at the terminal in the mid 1970's.

After certain assessment and remedial activities, VTSI endorsed a consent order with EPD in 2003. The consent order required preparation of a proper compliance status report (CSR) to fully address the remaining contaminated soils and groundwater associated with the PCE release. In addition, the consent order required the preparation and implementation of a corrective action plan (CAP) to remediate contaminated soil and groundwater. VTSI submitted a CAP with a projected 20-year cleanup schedule.

Based on subsequent remedial activities by VTSI, EPD notified VTSI in 2006 that the source soil remediation tasks were complete. The groundwater remediation program that involved an enhanced attenuation program was, however, found to be ineffective in reducing the overall extent of the groundwater plume. In 2010, VTSI retained Environmental International Corporation (EIC) to develop a more cost-effective remedial strategy to address the groundwater contamination. EIC proposed an alternative approach under the new Georgia Voluntary Remediation Program (VRP). In a letter dated August 31, 2011, EPD approved a voluntary investigation and remediation plan (VIRP) that presented the alternative approach. The approved VIRP superseded the requirements specified in the original consent order.

Immediately after the VIRP was approved, VTSI implemented the proposed assessment and remedial tasks. In implementing the tasks, EIC successfully completed a proper evaluation of the groundwater plume, demonstrated plume stability, reestablished monitored natural attenuation (MNA) with multiple lines of evidence, and substantially reduced the environmental risks. EIC also utilized a fate and transport model to demonstrate that any potential migration of the residual groundwater contamination will not impact the water quality of the Savannah River. To address the prevailing groundwater contamination, EIC proposed Type 5 risk reduction standards (RRS) as a contingency measure. In a stakeholder meeting, EPD and GPA concurred with VTSI that Type 5 RRS would be acceptable. VTSI also developed institutional controls to manage any potential risks from incidental exposure of groundwater during any site excavation activities within the groundwater plume. This CSR documents the results of the VIRP and petition's EPD to delist the site from the State of Georgia Hazardous Site Response Act (HSRA) Site Inventory.

## COMPLIANCE STATUS REPORT

## CERTIFICATION OF COMPLIANCE 391-3-19-.06(4)(a)

*"I certify under penalty of law that this report and all attachments were prepared under my direction in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations. Based on my review of the findings of this report with respect to the risk reduction standards of the Rules for Hazardous Site Response, Rule 391- 3-19-.07, I have determined that this site is in compliance with Type 5 risk reduction standards."*

# 1 INTRODUCTION

Vopak Terminal Savannah, Inc. (VTSI), in Savannah, Georgia is located on land leased from the Georgia Ports Authority (GPA). Prior to the 2000, VTSI was known as Paktank Corporation (Paktank).

The site is subject of a tetrachloroethene or perchloroethene (PCE) release that reportedly occurred while PCE was stored at the terminal in the mid 1970's. Over the years, the PCE has degraded into other dissolved chlorinated volatile organic compounds (CVOCs). The site is currently listed on the State of Georgia Hazardous Site Response Act (HSRA) Hazardous Site Inventory (HSI) as Site Number 10464, Paktank Corporation – Savannah Terminal (now known as VTSI).

In 1996, Paktank discovered a solvent release in the vicinity of Tank 24. Upon discovery, Paktank initiated certain assessment and remedial activities. In July 2003, VTSI endorsed a consent order No. EPD-HSR-384 issued by the Georgia Environmental Protection Division (EPD). The consent order required preparation of a proper compliance status report (CSR) to fully address the remaining contaminated soils and groundwater associated with the PCE release. In addition, the consent order required preparation and implementation of a corrective action plan (CAP) to remediate contaminated soil and groundwater (ERM, 2005). The CAP projected a 20-year cleanup time period.

Between 2001 and 2006, VTSI conducted a soil remediation program to address soil contamination at the source of the release. In a letter dated August 31, 2006, EPD acknowledged that the soil remediation program met Type 3 and 4 risk reduction standards(RRS). After implementing an enhanced attenuation program to address groundwater contamination, however, VTSI realized that the prevailing remedial process had minimal impact in reducing the overall extent of the groundwater plume.

In 2010, VTSI retained EIC to develop a more cost effective remedial strategy. After a thorough review of the site background data, EIC proposed an alternative approach under the new Georgia

Voluntary Remediation Program (VRP). The alternative approach outlined a pathway for conducting remediation in a more effective and timely manner.

On October 15, 2010, VTSI submitted a Revised Voluntary Remediation and Investigation Plan (VIRP) to the Georgia Environmental Protection Division (EPD). Based on comments from the EPD, VTSI submitted a revised VIRP on April 2, 2011. In a letter dated August 31, 2011, EPD approved the revised VIRP (EPD, 2011). The approved VIRP superseded the requirements specified in the original consent order No. EPD-HSR-384 issued by the EPD.

Immediately after the VIRP was approved, VTSI implemented the proposed tasks. In this Compliance Status Report (CSR), VTSI is documenting the results of the VIRP and the remedial progress. A completed checklist of items required in the CSR according to Georgia Administrative Code Rule 391-3-19-.06(3) is included as Attachment A.

## 1.1 SITE LOCATION AND DESCRIPTION

The site is located at Georgia Ports Authority Gate No. 2 on Turner and Hart Streets, with street address 280 Brampton Road, Garden City, Chatham County, Georgia 31418. The site has operated as a bulk storage facility since 1951. Historically, the terminal has stored various fuels and chemicals in various above-ground storage tanks (ASTs). The site is bordered by the GPA Port of Savannah Terminal property except to the eastern boundary where VTSI maintains docking facilities along the Savannah River. Beyond, a relatively narrow strip of GPA property along the southeastern edge of the site, lies an asphalt roofing materials manufacturing facility. Figure 1-1, in Exhibit G, illustrates the site layout. The warranty deed and tax plats of the site are included with Exhibit A, the VIRP (EIC, 2011).

SECTION 2

# 2 SITE CONCEPTUAL MODEL

A Site Conceptual Model (SCM), also known as Conceptual Site Model, is a summary of the site condition relative to a contaminant release. Typically, the model defines site characteristics, release sources, extent of the plume(s), likely fate and transport mechanisms, potential exposure pathways, and potential sensitive receptors that could be impacted. During the implementation of the VIRP, VTSI has refined and updated the SCM originally submitted in the VIRP. The following sections summarize the latest understanding of the SCM discussed in the Eighth Semi-annual Progress Report (EIC, 2015b), which is included as Exhibit E.

## 2.1 HYDROGEOLOGY

The site is underlain by a complex inter-bedded strata consisting of gravel, sand, silt, and clay lithology/soil types, and strata with various combinations of these soils. This results in a complex saturated soil matrix with anisotropic and non-homogeneous conditions as the pathway for groundwater flow. Based on historical gauging data from monitoring wells in the vicinity of the monitored constituents of concern (COC) plumes, the depth to groundwater ranges approximately from 1 to 10 feet below ground surface and groundwater generally flows from southwest to northeast. A full discussion of the site hydrogeology is presented in the SCM Report which is included in Exhibit E (EIC, 2015b).

## 2.2 CONSTITUENTS OF CONCERN

The primary COCs monitored at the site are CVOCs. These specifically consist of PCE and its degradation products trichloroethene (TCE), dichloroethene (DCE), and vinyl chloride (VC). Additionally, VTSI has investigated a historic release of volatile organic compounds (VOC) discovered in the same area of the site. The VOCs consist of benzene, toluene, ethylbenzene, and total xylenes (BTEX) and are comingled with the CVOCs. The delineation standards of these CVOCs and VOCs for groundwater are listed in Table 1-2 in Exhibit A (EIC, 2011).

## 2.3 RELEASE SOURCES

### 2.3.1 PCE Release

Referring to historic data, PCE was stored in Tank 24 during the period from December 1972 through April 1975 (ERM, 2010). In 1996, a PCE release was discovered in the vicinity of Tank 24. Since no PCE has been stored at the site since 1975, the release was attributed to previous terminal operations. Subsequently, the site's previous owners and VTSI have conducted various investigatory and remedial activities, per the EPD, including source removal. Due to natural attenuation, as noted in Section 2.2, the PCE has degraded into TCE, DCE, and VC.

### 2.3.2 Hydrocarbon Release

Based on the data presented in the CAP and from subsequent sampling events, it is apparent that BTEX constituents have been consistently detected in certain monitoring wells at the site where CVOCs are located (EIC, 2011). However, no documentation is available about the source of the BTEX.

## 2.4 Extent of Contamination

### 2.4.1 Soil Delineation

As documented in the VIRP, CVOC-contaminated soil in the vadose zone was delineated and remediated during the period from 2001 to 2006. A review of the analytical results from this activity indicated that BTEX contamination in the vadose zone was also delineated and remediated to CAP RRS. In a letter dated August 31, 2006, EPD concluded that soil at the site has met the established RRS (EPD, 2006).

### 2.4.2 Groundwater Delineation

During the implementation of the VIRP program, VTSI has delineated the extent of groundwater contamination. This effort required several improvements to the monitoring well network and collection of full round of groundwater samples during several sampling events. Explicit details of these activities were discussed in the corresponding semi-annual progress report and are summarized in Section 4 of this CSR. Table 3-4 in Exhibit G tabulates the historical groundwater analytical data for each well.

### 2.4.2.1 Horizontal Delineation

Chlorinated Volatile Organic Compounds

The horizontal extent of the dissolved CVOC plumes, during the baseline VIRP sampling event in October 2011, are illustrated in Figures 4 through 7 in Exhibit B. Following this event, VTSI installed 3 additional wells to provide additional data points for completing the delineation of COC plumes and to replace an un-located well. The CVOC plumes were further defined during the January 2014 sampling event, the first sampling event after the installation of 3 additional wells, as illustrated in Figures 4-7, 4-9, 4-11, and 4-13 in Exhibit C. Two of these wells served as downgradient sentinel wells enabling downgradient delineation of the CVOC plume. Following this event, one former injection well and one previously un-located well were both added to the sampled monitoring well network. As illustrated in Figures 3-3 through 3-6 in Exhibit G, from final VIRP sampling event in April 2016, samples collected from the improved monitoring well network, further defined the horizontal extent of the dissolved CVOCs. In reviewing the above CVOC plume maps, it is apparent that the CVOC plume has decreased in both concentration and extent during the VIRP program.

BTEX

The horizontal extent of the dissolved BTEX -from the baseline VIRP sampling event in October 2011 - is illustrated in Figures 8 through 11 in Exhibit B. Downgradient delineation of the BTEX plume has been complete since the initiation of the VIRP. Similar to the CVOC plume, the understanding of the BTEX plumes concentrations and extent were more accurately delineated with the expansion of the monitoring well network. Figures 4-15, 4-17, 4-19, and 4-21 in Exhibit C illustrate the extents of the BTEX plumes during January 2014, the first sampling event after the installation of 3 additional monitoring wells. Figures 3-7 through 3-10 in Exhibit G illustrate the horizontal extent of the BTEX plumes during the final VIRP sampling event in April 2016. In reviewing these figures, it is apparent that the BTEX plume has decreased in both concentration and extent during the VIRP program.

### 2.4.2.2 Vertical Delineation

The historical groundwater sampling results from the deep well MW-14 located within the original COCs footprint are tabulated in Table 3-4 in Exhibit G. Referring to the analytical data in the table, it is apparent that all monitored COCs concentrations in the well have remained below delineation standards since October 2013. Also, the concentrations of all but one parameter were below method detection limits - MDLs. In the EPD's comment letter to VTSI, dated April 3, 2014, the EPD concurred with VTSI that vertical delineation is complete (EPD, 2014).

## 2.5 FATE & TRANSPORT

The main purpose of determining potential exposure pathways is to assess the migration potential of the released COCs in a multimedia setting. Based on such an assessment, it is possible to establish potential exposure levels, critical in establishing risk-based screening and cleanup goals.

It would be expected that the released COCs at the site are subject to the following mechanisms:

- Physical phase separation of released liquid product into gas and other states of matter due to sorption, solubility and other equilibrium reactions.
- Dissolution of all or a portion of the product solute into the groundwater solvent. The portion of the product not dissolved is immiscible liquid.
- Advection referring to bulk movement of dissolved constituents and immiscible liquid.
- Dispersion involving horizontal and vertical spreading of partitioned constituents.
- Diffusion of the dissolved constituent in groundwater - consisting of spreading from concentration gradients.
- Biodegradation by native microorganisms of the dissolved constituent along the migration pathway.
- Other attenuation processes that reduce the dissolved concentrations with time and distance.

Due to multiple site factors, including: hydrogeology, variable co-metabolic degradation conditions, various engineered surface coverings and subsurface structures, and influence on groundwater by the Savannah River, accurate modeling of these mechanisms is not feasible. However, simplified estimations can be made from known and assumed conditions. A model based on these assumptions is detailed in the Ninth Semi-annual report (EIC, 2016), which is included as Exhibit F, and a summary is presented in Section 4 of this report.

## 2.6 MIGRATION PATHWAYS

### 2.6.1 CVOC Migration Potential

Typically, contaminants dissolved in groundwater tend to move in the direction of groundwater flow. Consequently, the location of the peak plume of the monitored dissolved concentrations of each monitored COC is expected to be subject to a migration consistent with seepage velocity. However, various interactions between contaminants, lithology, and groundwater can limit this

migration. Referring to the COC plume maps, it is apparent that the horizontal extent of all CVOCs have decreased since the October 2011 baseline sampling event and are confined within the baseline PCE foot-print.

### 2.6.2 VOC Migration Potential

The monitored COCs consisting of BTEX constituents are present within the CVOC plume footprint. The BTEX plume has also decreased over time and remains stable within the original PCE foot-print.

## 2.7 POTENTIAL RECEPTORS

Potential receptors are the most important drivers in establishing risk-based cleanup goals for the site. The receptors include human, ecological, natural resources, present and future land use, and down-gradient receptors.

### 2.7.1 Human Health Receptors

Since all contaminated soil that exceeded the RRS under the 2005 CAP within the vadose zone was previously excavated, as discussed in Section 3.1, subsurface soil lying above the water table is neither a concern to VTSI employees nor to construction workers at the site. Consequently, only groundwater contamination or saturated soils present potential human exposure at the site.

The 2005 CAP also states, "Because the site and surrounding area are served by a municipal water supply system, groundwater from the surficial aquifer at the site and within the vicinity of the site is not being used for human consumption. VTSI will also ensure that any construction works conducted within the area over contaminated groundwater will be limited to the extent of the vadose zone. Therefore, human exposure to contaminated ground water is an unlikely exposure pathway" (ERM, 2005). The CAP also states that there are no private drinking water wells within a two-mile radius of the VTSI site.

Nevertheless, if onsite workers need to excavate soils saturated with groundwater or groundwater during construction activities within the COC foot-print, VTSI will utilize institutional controls to monitor and protect workers. The institutional controls are described in more detail in Section 5.3.1.

### 2.7.2 Ecological Receptors

Referring to the 2005 CAP, the VTSI Savannah site was reviewed by the Georgia Natural Heritage Program (GNHP) to identify potential ecological receptors that may be impacted from contamination levels at VTSI. GNHP found no rare, imperiled, and critically imperiled plant and animal species at the site. Since the subject property is operated as an industrial facility, VTSI does not provide habitat for plants or animals. In addition, wetlands are not of concern at the VTSI site. According to the 2005 CAP, "With the exception of drainage ditches and other man-made depressions, no wetland-like areas were observed on the site." Therefore, no ecological receptors are affected by the COCs.

### 2.7.3 Present and Future Land Use

The subject property is currently utilized as a non-residential facility in a heavily industrialized setting. As stated in the introductory section, VTSI leased the property from GPA on a long-term lease. As such, the property will remain as a terminal for several decades. Upon lease expiration, the site property will continue to be utilized as a non-residential facility consistent with GPA's long-term plans for site redevelopment, local zoning, and deed restrictions.

### 2.7.4 Down-gradient Receptors

The GPA Port of Savannah container storage facility is located hydraulically down-gradient of the subject property. Groundwater samples collected from sentinel wells MW-35 and MW-36, located on GPA property and hydraulically down-gradient of the subject property indicates that COCs are well below delineation standards. Also, mixing zone calculations (discussed in Section 4.6) indicate no potential impact to the water quality standards in Savannah River.

SECTION 3

# 3 PREVIOUS REMEDIAL ACTION

In 2003, VTSI entered into a consent order with EPD to address soil and groundwater remediation. In 2005, EPD approved a CAP which included two important action items. The first action entailed prompt removal of the remaining source area, consisting of contaminated soil, to RRS standards. The second action entailed implementation of a groundwater remediation program to address dissolved CVOCs that were above RRS. The following sections summarize the soil and groundwater corrective actions.

## 3.1 Soil Remediation

From 2003 to 2006 soil removal and confirmatory sampling was completed with regards to source COCs at the site. In a letter dated August 31, 2006, EPD concluded that soil at the site met the RRS established under the CAP (EPD, 2006). Therefore, soil remediation of both CVOC and BTEX concentrations was completed prior to the initiation of the VIRP in 2011.

## 3.2 Groundwater Remediation

The CAP established a 20-year schedule to remediate the groundwater contaminated with CVOCs (ERM, 2010). The groundwater remediation entailed enhanced bioremediation with natural attenuation. In May of 2006, VTSI initiated the groundwater remediation program which included semi-annual injection of sodium, ethyl lactate, soybean oil, and pH buffer into 18 injection wells. The purpose of the injection program was to enhance reductive dechlorination of PCE. The injections were performed under an Underground Injection Control (UIC) Permit R-262, dated April 18, 2006, that expired on April 18, 2011 (ERM, 2010).

### 3.2.1 Performance of the Enhanced Bioremediation Program

The 2010 annual CAP report (ERM, 2010) presents the results of the enhanced natural attenuation program. During the attenuation program, groundwater samples were collected from monitoring wells located within and outside the plume boundary. Analytical results from the samples are tabulated in Table 3-4 in Exhibit G. As discussed in the VIRP, VTSI determined that the use of injection events to enhance bioremediation in groundwater at the site was not effective. As such, this approach was abandoned at the onset of the VIRP. In addition, upon an independent evaluation of the analytical results, VTSI determined that the enhanced natural attenuation program may have inhibited the natural attenuation potential of the CVOCs in groundwater.

SECTION

4

# 4 VIRP IMPLEMENTATION

Upon EPD's approval of the VIRP, VTSI terminated the enhanced attenuation program specified in the previous CAP and initiated the VIRP tasks to address the legacy groundwater contamination in a practical, cost effective manner. The following subsections describe the VIRP remedial strategy and executed actions.

## 4.1 REMEDIAL STRATEGY

A review of historical, groundwater monitoring data indicates that natural attenuation of COCs was occurring prior to the initiation of chemical injection events under the former CAP. Additionally, the prevailing COC plumes appeared to be stable and contained within the site. In implementing the VIRP strategy, VTSI properly delineated the extent of the plume and implemented a monitored natural attenuation (MNA) process to address the legacy groundwater contamination at the site

This strategy involved implementation of the following specific tasks:

- Termination of the injection program to allow the reestablishment of natural attenuation processes of the COCs.
- Evaluation and rehabilitation of the existing monitoring well network for proper delineation and consistent sampling of all wells.
- Development of new site-specific Risk Reduction Standards (RRS) for all COCs.
- Routine groundwater monitoring to evaluate plume attenuation, delineation and stability.
- Monitoring and evaluation of MNA indicator parameters.
- Development of a fate and transport model to evaluate the effectiveness of MNA and compliance with RRS.
- Contingency planning if MNA was discovered to be unsustainable in meeting RRS within the specified time frame of the VIRP.

## 4.2 MONITORING WELL NETWORK

As chronicled in the VIRP and in subsequent semi-annual progress reports, VTSI evaluated the conditions of the monitoring well network and their adequacy in properly defining the COC plumes. Based on the evaluation it was clear that some wells were deemed missing and others were either plugged or improperly abandoned. The historical monitoring data indicates that some of these wells were not available in previous sampling rounds for sample analysis. Consequently, VTSI found that historical data was inadequate in properly defining the extent of the COCs. Consequently, VTSI performed the following activities.

VTSI was able to survey the site to identify missing wells and properly abandoned wells that were no longer useful for monitoring due to downhole obstructions or silting. The extent of the monitoring well network at the beginning of the VIRP relative to the monitoring well network at the end of the VIRP program are illustrated in Figure 1 in Exhibit B and Figure 1-1 in Exhibit G, respectively. Well construction details for all wells utilized in the VIRP well network are included in Table 4-1.

The following sections detail the well network evaluation and improvements.

### 4.2.1 Identified Missing Wells

Wells MW-14 and MW-28, that were previously were reported missing, were located in October 2013 and October 2014, respectively. Subsequently, these wells were incorporated into the monitoring well network.

### 4.2.2 Abandoned Wells

Several wells that were either damaged, silted, lying in the path of new construction, or deemed unnecessary, were abandoned. Of those deemed unnecessary, two wells, which had been paved over, were located utilizing a licensed land surveyor (EIC 2014a). Abandonment procedures followed SESDGUID-101-R1 (EPA, 2013) and are detailed in the VIRP semi-annual progress reports (EIC 2012a, EIC 2014a, 2015a)

### 4.2.3 Installed New Wells

VTSI installed three new monitoring wells prior to the initiation of VIRP sampling in order to replace un-located or damaged wells (EIC, 2011). Three additional wells were installed in December 2013 for further delineation of the COC plume in areas that lacked adequate monitoring wells (EIC 2014a). Each of these wells was designed and installed per SESDGUID-101-R1 (EPA, 2013).

## 4.3 DEVELOPMENT OF RRS

In conformance with Georgia EPD Rule 391-3-19, VTSI updated Type 4 RRS values for the site from the 2005 CAP RRS values for the COCs utilizing EPA's Risk Assessment Guidance for Superfund (RAGS) equations 1 and 2. These RRS values were included in Table 4-1 in Exhibit A, the VIRP (EIC, 2011).

## 4.4 GROUNDWATER MONITORING PROGRAM

### 4.4.1 Groundwater Monitoring Objectives

The primary objectives of the VIRP groundwater monitoring program were to properly evaluate the plume, determine the plume stability, and monitoring the MNA remedial efficiency. These objectives were accomplished using data from routine groundwater monitoring events. The monitoring events were initially conducted on a quarterly basis and subsequently on a semi-annual basis. A total of 14 groundwater monitoring events and results are documented in the nine VIRP semi-annual progress reports (EIC, 2011 through EIC, 2015b). Since the final VIRP groundwater monitoring event was conducted in April 2016, the description of this event and the associated analytical results are detailed in Exhibit G.

### 4.4.2 Groundwater Sampling Protocol

Each groundwater monitoring/sampling event was conducted in accordance with the current U.S. Region 4 EPA groundwater sampling procedure "Field Branches Quality System and Technical Procedures" (FBQSTP) per EPD regulations. Each monitoring well was gauged, purged, and sampled following the "low-flow" purge and "soda straw" sampling techniques established in the current standard operating procedure (SOP) SESDPROC-301 under the FBQSTP (EPA, 2013).

### 4.4.3 Quality Control and Sample Custody

For each sampling event, VTSI stored all samples in insulated thermal containers ("coolers") with double-bagged ice, from the time samples were collected until they were relinquished to the laboratory. Trip blanks accompanied each cooler and were analyzed for indications of cross-contamination during transport. To prevent cross contamination, all sampling equipment was decontaminated following the current FBQSTP SOP SESDPROC-205 (EPA, 2015). Completed chain of custody forms accompanied each set of samples from collection until they were relinquished to the laboratory.

### 4.4.4 Laboratory Analysis

VTSI utilized a Georgia-certified laboratory perform all laboratory analyses of groundwater samples. Samples collected for VOC analysis were analyzed utilizing EPA Method 8260B. Groundwater samples collected for analysis of MNA indicator parameters were analyzed utilizing the respective analytical methods as discussed in Exhibit D, the Seventh VIRP Semiannual Monitoring Report (EIC, 2015a).

### 4.4.5 Groundwater Monitoring Results

#### 4.4.5.1 Groundwater Potentiometric Surface

Following each sampling event, VTSI computed groundwater elevations from gauging data to create groundwater potentiometric surface maps. Figure 3-1 in Exhibit G illustrates the groundwater potentiometric surface in April 2016. Table 3-5 in Exhibit G tabulates all groundwater elevation data collected during the implementation of the VIRP. In general, the data has consistently indicated a groundwater flow direction - in the vicinity of the COC plumes - from southwest to northeast.

#### 4.4.5.2 COC Sampling Results

Table 3-4 in Exhibit G tabulates the analytical results from each VIRP groundwater sampling event. From these results, VTSI prepared plume maps for each COC following each sampling event. For comparative purposes, only the plume maps from the October 2011, January 2014, and April 2016 sampling events are included in this CSR as Exhibits B, C, and G, respectively. These plume maps represent baseline, mid-point (after establishing monitoring well network), and final site conditions during the VIRP program. All other plume maps are included in the respective VIRP semi-annual progress reports submitted to the EPD.

### 4.4.6 Groundwater COC Evaluation

The baseline COC plumes of October 2011 representing site conditions at the initiation of the VIRP are shown in Exhibit B. Background groundwater concentration for each COC was determined to be zero during this event due to analytical results that were below detection limit for all COCs at several sentinel wells. After additional wells were progressively added to the network, as discussed in Section 4.2, new higher concentrations of COC were detected within the original COC foot-print - increasing the peak concentrations and the horizontal extent of several COCs. This is apparent from the figure included in Exhibit C, which illustrates plume conditions from the January 2014 monitoring event. Plume maps in Exhibit G illustrate the COC conditions that was defined from the final VIRP sampling event in April 2016.

In sequentially reviewing the COC plume maps, it first leads one to believe that both the horizontal extent and peak concentrations increased during the first half of the VIRP program. It is important recognize, however, the increase can be attributed to sampling data from new or missing wells that enabled a better definition of the original COC foot-print.

## 4.5 MNA PERFORMANCE

Even with the additional data points, it is apparent that the monitoring data indicates consistent reduction in the overall extent of the plume and plume stability during the VIRP program. Notably, COC concentrations wells MW-32 and MW-33 in the leading edge have reduced significantly, while COCs at a relatively small number of wells within the original foot-print remain recalcitrant. These wells include wells MW-29, LAW-PZ-8R, and IW-1R, which are located at the center of the COC plumes. It is also apparent from these figures that the COC plumes are fully delineated side- and down-gradient and have remained stable.

### 4.5.1 Multiple Lines of Evidence

During the implementation of the VIRP, multiple lines of evidence demonstrated the effectiveness of the MNA approach. This evidence was derived from spatial and temporal analyses of data obtained from both downhole monitoring and direct sampling events. The Fifth Semi-annual Report (EIC, 2014a) documents the results of the downhole MNA indicator parameter study. In a comment letter dated April 3, 2014, EPD concurred that the conditions reported by this study indicate that the COCs were conducive to natural attenuation (EPD, 2014).

As described in Exhibit D, the Seventh Semi-annual Progress Report (EIC, 2015a), samples were collected from select wells to measure MNA indicator parameters via laboratory analysis. The results of this sampling were presented alongside data collected by a multi-parameter water quality meter during routine groundwater sampling prior to and throughout the VIRP program. In a comment letter dated July 29, 2015, EPD concurred that these parameters confirmed that the subsurface environment was conducive to natural attenuation.

### 4.5.2 Statistical Evaluation

As discussed in the SCM (EIC, 2015b), spatial and temporal analysis have shown that contaminant plumes are stable and shrinking. Additionally, statistical trend analysis using the Mann-Kendall Method at several wells has shown a general decrease or stability of select COC concentrations. These concentration reductions support the original VIRP objective of reaching end points under the MNA approach. However, VTSI realized that additional time was required to reach Type 4 RRS standards due to recalcitrant concentrations in certain wells and from additional COC concentrations discovered after the addition of missing and new monitoring wells within the COC foot-print. As such, VTSI utilized a fate and transport model to consider contingency solutions.

### 4.5.3 Spatial and Temporal Evaluation

A spatial and temporal evaluation of sequential COC plume maps included in the semi-annual reports, clearly illustrate the effectiveness of the MNA reestablished during the VIRP implementation period. In addition, EIC utilized historical analytical data to compare the rate of PCE (source material) attenuation that took place pre-VIRP relative to the attenuation that was accomplished upon implementation of the VIRP. Figure 4-1 illustrates the comparative rate of PCE plume reduction in area weighted by the respective scale of plume concentrations. Referring to this figure, it is apparent that the overall reduction in PCE plume size during the VIRP was nearly 20% per year whereas the reduction prior to VIRP (under the old CAP) was less than 2%. This demonstrates that the VIRP successfully established the MNA.

## 4.6 FATE AND TRANSPORT MODEL

VTSI evaluated several two and three dimensional analytical models for the site. However, considering the heterogeneity and substructures that would lead to a complex fluid flow hydrodynamics, a more practical approach was essential to address potential impact of contaminated groundwater flow on downgradient receptors.

Clearly, the primary downgradient receptor would be the Savannah River which is subject to the Georgia Instream Water Quality Standard (EPD, 2013). As such, VTSI utilized a groundwater-to-river mixing model to determine the impact of groundwater contamination at the site on the Savannah River (River). This model utilizes groundwater flow, groundwater COC concentrations, and river flow rates to estimate the maximum potential COC concentrations in the Savannah River downstream of the site. The model evaluated several groundwater COC concentration scenarios to compute the resultant concentrations in the river water to national and state level regulatory limits. The following subsections discuss the general approach to the mixing model. A more in-depth discussion of the model inputs, calculations, and results is included in Exhibit F, the Ninth VIRP Semi-annual Progress Report (EIC, 2016).

### 4.6.1 Model Setup

Utilizing the aquifer parameters collected at the site (hydraulic conductivity, hydraulic gradient, etc.), VTSI developed a groundwater-to-river mixing model based on the Dupuit Equation for estimating steady flow through an unconfined aquifer (EIC, 2016). For the model inputs, VTSI assumed the following: the entire mass of groundwater leaving the site is uniformly contaminated, groundwater enters the River along the entire length of the site, and groundwater completely mixes with surface water in the River.

In estimating the resulting downstream river concentrations, VTSI utilized three sets of COC concentrations ranging from current site conditions (i.e. at the leading edge) to a worst-case scenario

(i.e. maximum concentration ever recorded at the site) to compute varying degrees of potential downstream concentrations. These are presented in the Ninth VIRP Semi-annual Progress Report (EIC, 2016) presented as Exhibit F.

### 4.6.2 Results

The results the model calculations were compared with the state and national regulatory levels for each COC. The regulatory levels considered for this evaluation are the Georgia Instream Water Quality Standard (EPD, 2013) and the National Primary Drinking Water Standard (EPA, 2009).

These modeled downstream River concentrations are several orders of magnitude lower than the state or federal regulatory standards. As such, it is apparent that the potential impact from groundwater discharge from the site into the River would be negligible. Considering that this is a conservative worst-case scenario, potential COC migration to the River from this site would not result in downstream River concentrations in excess of either federal or state surface water quality standards.

## 4.7 VAPOR INTRUSION POTENTIAL

As noted in Section 3.1, CVOC-contaminated soil in the vadose zone was previously delineated and remediated and EPD has concluded that soil at the site has met the established RRS (EPD, 2006). In addition, the residual COC concentrations in the groundwater are substantially low to present a vapor risk. In reviewing the extent of the COC plume, it is also apparent that no enclosed structures are present within the COC foot-print. Consequently, the only potential vapor risk would be incidental contact of contaminated groundwater to construction workers. VTSI will manage these risks with institutional controls as described in Section 5.3.1.

SECTION 5

# 5 REMEDIAL COMPLIANCE

Based on the site monitoring data, it is clear that VTSI successfully reestablished the MNA process during the implementation of the VIRP. As discussed in Sections 4.5, the COC plume is well contained and is attenuating at a reasonable reduction rate. Additional time is, however, required for the residual COCs to reach Type 4 RRS levels. Consequently, VTSI initiated contingency planning process outlined in the VIRP to evaluate an alternative remedial strategy for the residual COCs. One of the alternatives involve consideration of Type 5 RRS standards as a remedy.

## 5.1 TYPE 5 RRS

As discussed in the aforementioned sections, the COC plume is contained and attenuating. The results of the fate and transport model, discussed in Section 4.6, indicates that potential migration of dissolved COC in groundwater will not impact the water quality of the Savannah River. As discussed in the site conceptual model, the only remaining risk would be potential incidental contact of contaminated groundwater to construction workers. These types of exposure are only expected to occur during activities such as soil excavation. VTSI can use institutional controls to prevent potential exposure to construction workers. Considering that VTSI has a long term lease with GPA on the subject property, continued MNA would enable VTSI to reach remedial end points within a reasonable time frame. As such, VTSI elected to pursue Type 5 RRS option as a contingency measure in accordance with the terms of the VIRP.

## 5.2 STAKEHOLDER ENDORSEMENT

VTSI presented the Type 5 RRS option to GPA (site owner) and obtained endorsement. Subsequently, EIC arranged a joint stakeholder meeting between VTSI, GPA, and EPD. In a that meeting held at the EPD office, on February 25, 2016, EIC presented the results of the VIRP program and proposed Type 5 RRS as a site remedy for the residual COC. EPD acknowledged that such an option would be feasible and directed VTSI to prepare a compliance status report (CSR) along with a Uniform Environmental Covenant (UEC) to address the prevailing site risks.

## 5.3 UNIFORM ENVIRONMENTAL COVENANT

The UEC requires engineering and or institutional controls to manage potential risks - such as the residual contamination remaining at the site. Considering that the site is a regulated and secure facility with controlled access, no additional engineering controls would be required to manage the environmental risks. Nonetheless, VTSI requires all contractors and site workers to comply with site specific health and safety requirements and all site work is controlled with issuance of work permits. VTSI will update these procedures in order to ensure that any contractors involved in excavation activities is aware of the exposure risks and follows proper health and safety protocols. This process will therefore serve as institutional controls. The following protocol has been developed to implement institutional controls.

### 5.3.1 Institutional Controls

The modified work permit to be issued by VTSI to contractors will notify contractors that special stipulations apply for any excavation activities within the residual COC foot-print. The UEC will include a figure clearly illustrating the extent of the COC foot-print. Construction workers performing excavation or subsurface utility work that may result in exposure to groundwater in the designated areas would be required to meet appropriate health and safety training and perform the work in accordance with a Health and Safety Plan prepared by a qualified environmental/safety professional. The permit will also stipulate that any extracted groundwater should not be discharged into the storm water system or surface waters. Instead, any impacted groundwater extracted from the site will be managed in accordance with all applicable local, state and federal rules and regulations governing the management of such material.

Any future development of the property with enclosed structures in the area covered by the residual COC foot-print will be required to conduct a vapor intrusion evaluation and implement appropriate vapor mitigation system or barrier. Upon installation, such vapor management systems will be properly maintained, until the regulated substances in soil and groundwater at the site reach Type 4 RRS; or until vapor modeling of groundwater indicates that vapor mitigation is not required for enclosed structures and EPD concurs with the vapor modeling results.

## 5.4 PETITION TO DELIST

Based on this CSR, please note that the site is in compliance with Georgia's Type 5 risk reduction standards (RRS) for groundwater cleanup. Consequently, VTSI petition's EPD to delist the site from the State of Georgia Hazardous Site Response Act (HSRA) Site Inventory.

| 391- 3-19-.06(3)(b)(2)(vii) | Narrative and tabular summary of all pertinent field data and the results of all final lab analyses that are supported by sufficient QA/QC control data to validate the results. | - | - |
| | **Releases to Groundwater** | | |
| 391- 3-19-.06(3)(b)(3) | Complete definition of horizontal and vertical extent of groundwater contamination to background. Background shall be determined using samples representative of groundwater conditions not affected by a release of a regulated substance. In support of the definition of the extent of contamination, the CSR shall include, at a minimum: | Y | pg. 4-5 |
| 391- 3-19-.06(3)(b)(3)(i) | Analytical parameters selected and the rationale for selection; | Y | pg. 3 |
| 391- 3-19-.06(3)(b)(3)(ii) | A description of methods used to characterize sub-surface geology; | Y | pg. 3 |
| 391- 3-19-.06(3)(b)(3)(iii) | A description of methods used to characterize vertical and horizontal groundwater flow gradients, flow rates, and flow directions; | Y | pg. 3 |
| 391- 3-19-.06(3)(b)(3)(iv) | Methods used to determine hydraulic conductivities and other pertinent hydrogeological characteristics, including a description of any slug and/or aquifer tests; | Y | pg. 3, Appendix A in Exhibit E |
| 391- 3-19-.06(3)(b)(3)(v) | A description of groundwater monitoring well locations, and their installation and construction methods, including: | Y | Figure 1-1 in Exhibit G, Table 4-0 |
| 391- 3-19-.06(3)(b)(3)(v)(I) | A map (minimum scale 1"= 200') depicting all existing well locations including a survey of each well's surface reference point and the elevation of its top-of-casing; | Y | Figure 1-1 in Exhibit G, Table 4-1 |
| 391- 3-19-.06(3)(b)(3)(v)(II) | Type of well casing material; | Y | Table 4-1 |

| RULE SECTION | DESCRIPTION OF REQUIREMENT | Y or [-] | Location in CSR (i.e. pg.) |
|---|---|---|---|
| 391- 3-19-.06(3)(b)(3)(v)(III) | Description of well intake design including screen slot size and length, filter pack materials and length, and method of filter pack emplacement; | Y | Table 4-1 |
| 391- 3-19-.06(3)(b)(3)(v)(IV) | Method used to seal the well from the surface and any other features designed to prevent or minimize downward migration of contaminants along the well annulus; and | Y | Table 4-1 |
| 391- 3-19-.06(3)(b)(3)(v)(V) | Description of methods and procedures used to develop the wells. | Y | Table 4-1 |
| 391- 3-19-.06(3)(b)(3)(vi) | Description of all sampling and analysis procedures used including: | Y | pg. 13 |
| 391- 3-19-.06(3)(b)(3)(vi)(I) | Procedures and timing for measuring groundwater elevations for each sampling event; | Y | pg. 13 |
| 391- 3-19-.06(3)(b)(3)(vi)(II) | Well evacuation procedures including well volume evacuated prior to sampling; | Y | pg. 13 |
| 391- 3-19-.06(3)(b)(3)(vi)(III) | Sample withdrawal techniques, sampling equipment and materials; | Y | pg. 13 |
| 391- 3-19-.06(3)(b)(3)(vi)(IV) | Sample handling and preservation techniques; | Y | pg. 13 |
| 391- 3-19-.06(3)(b)(3)(vi)(V) | Equipment decontamination procedures; | Y | pg. 13 |
| 391- 3-19-.06(3)(b)(3)(vi)(VI) | Chain-of-custody procedures; | Y | pg. 13 |
| 391- 3-19-.06(3)(b)(3)(vi)(VII) | Lab techniques including references to analytical methods, including QA/QC procedures; | Y | pg. 13 |
| 391- 3-19-.06(3)(b)(3)(vii) | Description of procedures used to determine background groundwater concentrations; | Y | pg. 14 |
| 391- 3-19-.06(3)(b)(3)(viii) | Map (minimum scale of 1" = 200') or less depicting the horizontal extent of contamination. Concentrations should be indicated by isoconcentration lines. | Y | Figures 3-3 to 3-10 in Exhibit G |
| 391- 3-19-.06(3)(b)(3)(ix) | Map (minimum scale of 1" = 200') or less depicting the potentiometric surface of groundwater; | Y | Figure 3-1 in Exhibit G |
| 391- 3-19-.06(3)(b)(3)(x) | Maps and vertical cross-sections of appropriate scale depicting concentrations for all contaminants superimposed upon site stratigraphic features and monitoring wells; and | Y | Appendix A in Exhibit E |
| 391- 3-19-.06(3)(b)(3)(xi) | Narrative and tabular summary of all pertinent field data and the results of all final lab analyses that are supported by sufficient QA/QC control data to validate the results. | Y | pg. 14 |
| **Additional Requirements** | | | |
| 391- 3-19-.06(3)(b)(4) | A description of any human or environmental receptors who may have been or could potentially be exposed to a release at the site. | Y | pg. 7-8 |
| 391- 3-19-.06(3)(b)(5) | A description of all properties which are part of the site including the address and location of such property, its legal description, and the property owner's name, address and telephone number. | Y | Exhbit A |
| 391- 3-19-.06(3)(b)(6) | The name, address, and telephone number of any other person who may be a responsible party for the site and a description of the type and amount of regulated substances such party may have contributed to a release. | - | - |
| 391- 3-19-.06(3)(b)(7) | A summary of previous actions taken to eliminate, control or minimize any potential risk at the site, including actions taken to comply with the risk reduction standards. | Y | pg. 9-10 |
| 391- 3-19-.06(3)(b)(10) | Attached to the front of the CSR, concise statement of the findings of the report presented in plain language, immediately followed by the certification required by 391-3-19-.06(4)(a). | Y | Cover page |
| 391-3-19-.06(4)(a) | The CSR shall include a compliance certification regarding the responsible party's own determination as to the status of a site or any individual property at a site with regard to the applicable risk reduction standards for all regulated substances evaluated by the CSR. | Y | Certification Page |
| 391-3-19-.06(4)(b) | The CSR certification shall be signed by the applicable person described in Items 1 - 4 of .03(6)(c). Where the CSR is submitted for two or more cooperating responsible parties, the certification may be signed by a duly authorized representative of said responsible parties. | Y | Certification Page |
| 391-3-19-.06(4)(c) | Any person signing the certification of compliance shall make the certification specified in the Rules. | Y | Certification Page |
| 391- 3-19-.06(5)(a) | Within 7 days of submitting the CSR, RP shall publish a notice in both a major local newspaper of general circulation and the legal organ of the local governments in whose jurisdiction the site is located, announcing that such a report is available for inspection by the general public, including: | Y | - |
| 391- 3-19-.06(5)(a)(1) | The name, address, and location of the site as it appears on the HSI, and, if the plan applies to less that the full site, the street address and owner's name of the applicable properties; | Y | - |

| RULE SECTION | DESCRIPTION OF REQUIREMENT | Y or [-] | Location in CSR (i.e. pg.) |
|---|---|---|---|
| 391- 3-19-.06(5)(a)(2) | The statement provided in this section; | Y | - |
| 391- 3-19-.06(5)(a)(3) | Announcement of a 30-day comment period and the name, address, and phone number of the EPD contact person to whom written or oral comments can be made; | Y | - |
| 391- 3-19-.06(5)(a)(4) | Name, address, and phone number of the RP or its designated contact person; and | Y | - |
| 391- 3-19-.06(5)(a)(5) | Location where the report may be viewed or copied. | Y | - |
| 391- 3-19-.06(5)(e) | Within 7 days of submitting the CSR to EPD, the RP shall provide to the count government in the county in which the site is located and to the government of any city in whose jurisdiction the site is located the same information required above. | Y | - |
| 391-3-19-.07(4) | For corrective action to be in compliance with these standards, the following common elements are required: | Y | - |
| 391-3-19-.07(4)(a) | Removal of all free product to the extent practicable. | Y | - |
| 391-3-19-.07(4)(b) | No soil remaining in place shall exhibit the hazardous waste characteristics of ignitability, corrosivity, or reactivity. | Y | pg. 4 |
| 391-3-19-.07(4)(c) | Shall not allow exposure to concentrations which would cause food chain contamination, damage to soils or to biota which could impair the use of the soils for agricultural or silvicultural purposed, adverse effects on vegetation or wildlife, or the accumulation of vapors in buildings or other structures which pose a threat to human health and the environment | Y | pg. 7-8, 15-17 |
| 391-3-19-.07(4)(d) | Shall protect the waters of the State from releases that would cause surface water to exceed the Georgia in-stream water quality standards. | Y | PG. 15-17 |
| 391-3-19-.07(4)(e) | If the detection limit and/or the background concentration for a regulated substance is greater than the concentration specified in any risk reduction standard, the greater of the detection limit or background shall be used for determining compliance with the risk reduction standards. | - | - |

SECTION 1

# 1 INTRODUCTION

The Vopak Terminal Savannah (VOPAK), in Savannah, Georgia is located on land leased from Georgia Ports Authority. Prior to VOPAK's acquisition in 1992, the terminal was operated by Paktank Corporation.

The site is subject of a tetrachloroethene or perchloroethene (PCE) release. Over the years, the PCE has degraded into other dissolved chlorinated volatile organic compounds (CVOCs). The site is currently listed on the State of Georgia Hazardous Site Response Act (HSRA) site inventory as Site Number 10464, Paktank Corporation – Savannah Terminal (now known as VOPAK).

VOPAK is currently addressing the PCE release under consent order No. EPD-HSR-384 issued by the Georgia Environmental Protection Division (EPD). The consent order involved implementation of an approved corrective action plan (CAP) (ERM, 2005). The CAP projected a 20-year cleanup time period.

This application to the EPD's Voluntary Remediation Program (VRP) was prepared to define a pathway for conducting remediation in a more effective and timely manner. Once approved, the VRP standards will supersede the CAP requirements. The completed VPR Application form and checklist is in Attachment A.

The following sections address the elements of the VRP application criteria. The material used in preparing this application was primarily derived from activities performed in compliance with the EPD approved CAP.

## 1.1 SITE LOCATION AND DESCRIPTION

The physical site address is the Georgia Ports Authority Gate No. 2 on Turner and Hart Street, Garden City, Savannah, Georgia. The site, located in Chatham County, has operated as a bulk storage facility since 1951. Historically the terminal stored various fuels and chemicals. The area surrounding the site consists of a latex products storage facility to the north, an asphalt roofing materials manufacturing facility and the Savannah River to the east, and the Georgia Port Authority

container storage facility to the west. Figure 1-1 depicts the site location. The warranty deed for the site is located in Attachment B. The tax plats of the site are located in Attachment C.

## 1.2 SITE HYDROGEOLOGY

According to the CAP, the site is underlain by silty sands and clays to a depth of approximately 17 feet below ground surface (bgs). Two geologic cross-sections from the CAP illustrate the subsurface. Figure 1-2 depicts the cross section traces in plan view. Cross Section A-A' (Figure 1-3) extends south to north and Cross Section B-B' (Figure 1-4) extends east to west. Based on historical gauging data, depth to groundwater ranges approximately from 4 to 11 feet below ground surface. A groundwater potentiometric surface map (Figure 1-5), prepared by ERM for the recent CAP annual report (ERM, 2010), indicates a northerly to northeasterly direction of ground water flow at the site.

Estimates of the hydraulic gradient at the site ranges from 0.0145 to 0.0133. Hydraulic conductivity was determined to range from 3.09 x 10-4 cm/sec to 4.31 x 10-5 cm/sec, and the estimated seepage velocity to be approximately 21 to 23 feet per year (CAP).

## 1.3 COC & DELINEATION STANDARDS

The primary contaminants of concern (COC) at the site are CVOCs. As discussed in Section 2.1, the PCE released at the site has degraded into other CVOCs. Additionally, VOPAK is currently investigating historic volatile organic compounds (VOC) discovered at the site. The delineation standards for soil and groundwater are listed in Tables 1-1 and 1-2.

## 1.4 RISK REDUCTION STANDARDS

In accordance with EPD rules, VOPAK developed Type 3 risk reduction standards (RRS) for soil and Type 4 RRS for groundwater as delineation standards. According to ERM, EPD approved both standards for the site (ERM, 2002).

### 1.4.1 RRS for Soil

In 2003, VOPAK developed Type 4 RRS for soils (ERM, 2003). After successive iterations, between 2003 and 2004, EPD approved the final RRS for soils. VOPAK utilized the soil RRS to delineate the horizontal and vertical extent of soil contamination. As discussed in section 3.1, VOPAK remediated soils that exceeded the soil delineation standards. All source material exceeding the soil delineation standards was therefore removed from the site.

### 1.4.2 RRS for Groundwater

In 2005, EPD approved revised Type 3/4 RRS for groundwater (EPD, 2005). Table 1-3 lists the current RRS approved in the CAP. Subsequently, VOPAK initiated a groundwater remediation program as discussed in Section 3.2.

SECTION 2

# 2 SITE CONCEPTUAL MODEL

A Site Conceptual Model (SCM), also known as Conceptual Site Model, is a summary of the site condition as it pertains to a contaminant release. Typically, the model defines release sources, extent of the plume, likely fate and transport mechanisms, potential exposure pathways, and potential receptors that could be impacted. This information serves as an important tool in developing site remedies. The following sections provide a preliminary SCM based on available site data. As additional knowledge is gained, during the implementation of the VRP, VOPAK will further refine the SCM.

## 2.1 RELEASE SOURCES

### 2.1.1 PCE Release

PCE was stored in Tank 24 during the period December 1972 through April 1975 (CAP). In 1996, a PCE release was discovered in the vicinity of Tank 24. Since no PCE has been stored at the site since 1975, the release was attributed to previous terminal operations. Subsequently, the site's previous owners and VOPAK have conducted various investigatory and remedial activities per the EPD, including source removal.

Due to natural attenuation, the PCE has degraded into trichloroethene (TCE), dichloroethene (DCE), and vinyl chloride (VC). Therefore, both PCE and these daughter products are the main chemicals of concern at the facility. All four of these chemicals are CVOCs. Table 2-1 lists the analytical results of CVOCs monitored during the period Feb 1991 through September 2009.

### 2.1.2 BTEX Release

Based on the recent annual CAP report (ERM, 2010), it is apparent that certain VOCs consisting of benzene, toluene, ethylbenzene, and xylenes (BTEX) have been consistently detected in certain monitoring wells at the site. The BTEX analytical results monitored for the period from December 1998 through September 2009 from the recent CAP annual report are presented in Table 2-2.

To determine the source of the BTEX, VOPAK reviewed the historic data collected at the site. A brief summary of this review is included in Attachment D. Based on the review, it is clear that three well-defined dissolved BTEX plumes were identified back in 1996. The first plume was located within the same foot-print as the current PCE plume. The second BTEX plume, located to the west of the first plume, was separated by a distance of more than 1,000 feet. A smaller third BTEX plume was located approximately 400 feet to the north west of the second plume. The sources of these plumes were not apparent from the available documents.

On January 12, 1999, a major diesel release took place from AST 22 that resulted in LPH accumulations at the second and third plumes. VOPAK is currently performing diesel remediation in these areas in compliance with EPD requirements specified by the Watershed Protection Branch.

## 2.2 EXTENT OF PCE PLUME

### 2.2.1 Soil Delineation

Soil contamination resulting from the PCE release was delineated during the period from 2001 to 2006. A review of the analytical results from this activity indicated that BTEX concentrations were also delineated within the area impacted by PCE release. As discussed in Section 3.1, soil excavation within the PCE footprint met RRS standards for both CVOCs and BTEX concentrations.

### 2.2.2 Groundwater Delineation

Chlorinated Volatile Organic Compounds

Figures 2-1 through 2-4 illustrate the horizontal extent of the dissolved CVOCs relative to the groundwater delineation concentrations listed in Table 1-2. In reviewing the figures, it appears that the dissolved CVOC plume is confined to a relatively small area within the tank farm where the original PCE release took place. Referring to the historic data, it is apparent that the CVOC plume has remained stable in this area. VOPAK is currently evaluating both the horizontal and vertical extent of the CVOCs plume.

Dissolved CVOC concentrations of PCE, TCE, 1,2-DCE, and vinyl chloride currently meet the established RRSs in the CAP in all but seven wells, namely PAN-MW-9, LAW-PZ-8, MW-16, MW-22/22R, MW-24/24R, MW-26/26R, and MW-29. Referring to Table 2-1, the following observations of groundwater RRS exceedences are noted:

- CVOC concentrations in LAW-PZ-8, MW-22/22R, and MW-29 currently exceed the RRSs for PCE, TCE, 1,2-DCE, and vinyl chloride
- Concentrations in PAN-MW-9 and MW-24/24R currently meet all the RRS except for PCE, TCE, and vinyl chloride
- Concentrations in MW-16 and MW-26/26R meet all the RRS except for vinyl chloride

- The PCE concentration in LAW-PZ-8, that was 70 ppb in October 2003, increased to 300 ppb in October 2006, and has fluctuated between 99 and 570 ppb between October 2006 and September 2009. Similarly, the PCE concentration, in MW-24/24R, that was 97 ppb in October 2003, increased to as high as 1,300 ppb in June 2006, however it has decreased to 93 ppb.
- The PCE concentrations in MW-22/22R are the highest of the sampled wells at 3,000 ppb.

BTEX

Figures 2-5 through 2-8 illustrate the horizontal extent of BTEX concentrations, within the PCE foot-print, relative to the groundwater delineation concentrations listed in Table 1-2. Similar to the dissolved CVOCs, the dissolved BTEX plume in the PCE footprint also appears confined to a relatively small area within the tank farm where the original PCE release took place. Referring to the historic data, (Attachment D), it is apparent that the BTEX concentrations have significantly reduced in this area. VOPAK is currently evaluating both the horizontal and vertical extent of the dissolved BTEX plumes, in the area to the west of the PCE plume, under a separate program regulated by the EPD's Watershed Protection Branch.

## 2.3 FATE & TRANSPORT

The main purpose of determining potential exposure pathways is to assess the migration potential of the released COC in a multimedia setting. Based on such an assessment, it is possible to establish potential exposure levels, critical in establishing risk-based screening and cleanup goals.

It would be expected that the released COCs at the site are subject to the following mechanisms:

- Physical separation of released product into gas and other states of matter due to sorption, solubility and other equilibrium reactions.
- Advection referring to bulk movement of the immiscible liquid.
- Dispersion involving horizontal and vertical spreading of partitioned constituents.
- Diffusion consisting of spreading from concentration gradients.
- Biodegradation by native microorganisms along the migration pathway.
- Other attenuation processes that reduce the concentrations with time and distance.

The PCE release was terminated upon discovery and has not been stored at the site since 1975. According to the 2005 CAP, there are two main transport mechanisms of exposure occurring at the site. These included leachate from contaminated soils that act as source material and transport of leachate in the groundwater medium. However, leachate is no longer a concern at the VOPAK site, because the contaminated soil was excavated in 2006 (EPD, 2006). As such, at this site, the primary mechanisms affecting the exposure pathways of COCs are advection, dispersion, diffusion, and biodegradation.

## 2.4 MIGRATION PATHWAYS

Based on previous investigations, it is apparent that dissolved VOCs are the primary COC. The following sections outline both the CVOCs and VOCs that are currently under investigation.

### 2.4.1 CVOC Migration Potential

Typically, dissolved contaminants tend to move with the groundwater flow. Consequently, the peak plume would be subject to a migration consistent with seepage velocity. The PCE plume, illustrated in the sequential maps in Figure 2-9 has not migrated in the direction of ground water flow. Referring to Figure 2-9, however, it is apparent that the peak plume has remained stable in the vicinity of Tanks 32 and 34. As such, there appears to be no immediate down-gradient receptors of contaminated groundwater adjacent to the site. Further evaluation of the trends of the target contaminants will be conducted as described in the projected milestone schedule (Section 5).

### 2.4.2 VOC Migration Potential

Volatile organic compounds primarily composed of BTEX constituents are present within the PCE plume foot-print primarily in wells PAN-MW-9 and LAW-PZ-8/8R (ERM, 2010) and, as such, would likely be subject to similar hydrodynamic mechanisms as those that affect the PCE plume. VOPAK is currently evaluating the VOC migration potential of BTEX in the remaining areas. The results from a property-wide groundwater sampling event from all site wells will be utilized to identify potential source(s) and migration potential.

## 2.5 POTENTIAL RECEPTORS

### 2.5.1 Human Health Receptors

Since all contaminated soil that exceeded the RRS was excavated in 2006, as discussed in Section 3.1, subsurface soil is neither a concern to VOPAK employees nor to construction workers at the site. Consequently, only groundwater contamination presents potential human exposure at the site. When addressing groundwater exposure receptors, the 2005 CAP states, "Because the site and surrounding area are served by a municipal water supply system, groundwater from the surficial aquifer is not being used for human consumption. VOPAK will also ensure that any construction works conducted within the area covering contaminated groundwater will be limited to the extent of the vadose zone. Therefore, human exposure to contaminated ground water is an unlikely exposure pathway" (CAP). The CAP also states that there are no private wells within a two-mile radius of the VOPAK Terminal site.

### 2.5.2 Ecological Receptors

According to the 2005 CAP, the VOPAK Savannah site was reviewed by the Georgia Natural Heritage Program (GNHP) to identify potential ecological receptors that may be impacted from contamination levels at VOPAK. GNHP found no rare, imperiled, and critically imperiled plant and animal species at the site. Due to its entity as an industrial facility, VOPAK does not provide habitat for plants or animals. In addition, wetlands are not of concern at the VOPAK site. According to the 2005 CAP, "With the exception of drainage ditches and other man-made depressions, no wetland-like areas were observed on the site" (CAP).

## 2.6 OTHER PATHWAYS

As discussed in Section 2.4, groundwater is the primary pathway for migration of COCs is the primary pathway at this site. Upon completion of the horizontal and vertical delineation of COCs, proposed in this VRP, potential for migration through other media such as surface water, air, soil, and sediment will be evaluated. Figure 2-10 illustrates potential pathways through which the COCs can migrate. VOPAK will in particular evaluate the vapor intrusion potential to ensure that terminal personnel, contactors are not at risk of exposure.

## 2.7 MODEL LIMITATIONS

The preliminary SCM, outlined in Section 2, describes the site condition based on available site data. During the VRP process, VOPAK will calibrate the SCM based on additional findings.

If sufficient data is available, a three-dimensional rendering of the contaminant plume can be developed. Considering that the data pertaining to horizontal and vertical delineation were obtained from different monitoring dates, such a rendering was impractical for this site. VOPAK, however, included two-dimensional rendering of horizontal and vertical delineation in Section 2.2.

SECTION 3

# 3 CURRENT REMEDY

In 2003, VOPAK entered into a consent order with EPD to address soil and groundwater remediation. In 2005, EPD approved a CAP which included two important action items. The first action entailed prompt removal of the remaining source area contaminated soil to RRS standards. The second action entailed implementation of a groundwater remediation program to address dissolved CVOCs that were above RRS. The following sections summarize the soil and groundwater corrective actions.

## 3.1 SOIL REMEDIATION

According to the Final Soil Removal Closure Report and Compliance Status Report (CSR) Addendum (ERM, 2006), soil contaminated with CVOCs was successively removed from the site during three separate events in 2003, 2005, and 2006.

In May and June of 2003, approximately 54 cubic yards of soil was removed from a 320 square feet area along the northeast side of a containment dike with backhoe equipment around Tanks 23 through Tank 52. Soil samples collected after the excavation indicated that additional excavation was needed, as soils above RRS remained.

From January through March of 2005, approximately 1,950 tons of soil was removed from 180 linear feet of containment dike and 300 linear feet of drainage swale/railroad (paralleling the containment dike) along the northeast side and inside of the containment dike. Soil was excavated using both hand and machine methods to the depth of the water table, a depth ranging from 3 to 5 feet. Excavation was stopped where sidewall confirmation samples indicated that RRSs were met. A total of 18.5 tons of soil was sent to the Waste Management facility in Emelle, Alabama as hazardous waste and the remaining 1,931.5 tons was delivered to the Waste Management Superior Landfill in Savannah, Georgia.

In April 2006, approximately 108 tons of soil was removed from a 35-feet excavation along another railroad at a loading rack south of Tank 24. Much of the soil to the depth of the water table was excavated by hand due to presence of product lines and electrical conduits. The soil was delivered to the Waste Management Superior Landfill in Savannah, Georgia.

Upon completion of the 2006 soil removal activities, VOPAK submitted a report documenting the site activities. In a letter dated August 31, 2006, EPD concluded that soil at the site met the established RRS (EPD, 2006).

Analytical results from the confirmation samples obtained from PCE soil cleanup indicates that the cleanup also resulted in removal of BTEX contaminated soils since it was present within the same footprint as the PCE release. Therefore, RRS standards were achieved for BTEX concentrations at this location.

Soil remediation of both CVOC and BTEX concentrations are therefore complete in the PCE footprint.

## 3.2 GROUNDWATER REMEDIATION

The CAP established a 20-year schedule to remediate the groundwater contaminated with CVOCs (CAP). The groundwater remediation entailed enhanced bioremediation with natural attenuation. In May of 2006, VOPAK initiated the groundwater remediation program which entailed periodic injection of sodium, ethyl lactate, soybean oil, and pH buffer into 18 injection wells. The purpose of the injection program was to enhance reductive dechlorination of PCE. The injections were performed under an Underground Injection Control (UIC) Permit R-262, dated April 18, 2006, that is set to expire on April 18, 2011 (ERM, 2010). Currently the injections are conducted semi-annually.

## 3.3 PERFORMANCE OF THE GROUNDWATER REMEDIATION PROGRAM

The current groundwater remediation program entails enhanced bioremediation with natural attenuation to reduce the target contaminants. The recent annual CAP report (ERM, 2010) presents the results of the enhanced natural attenuation program. During the attenuation program, groundwater samples were collected from monitoring wells located within and outside the plume boundary. Analytical results from the samples are tabulated in Tables 2-1 and 2-2.

### 3.3.1 Bioremediation Rates

A table in ERM's CAP third annual report (ERM, 2010) claimed a 27% to 97% decrease in target contaminants. A closer examination of the data, however, indicates that the concentrations have fluctuated up and down since chemical injection was initiated. For instance, as shown in Figure 3-1, the PCE concentrations in PAN-MW-9 reduced from 14,000 to 80 ppb (a 99% decrease) between February 1991 and August 2005 from natural attenuation prior to an enhanced remedial approach. Subsequently, during the full-scale injection of chemicals, designed for enhance attenuation, the PCE actually increased to as high as 1,900 ppb, reversing the decreasing trend. A similar trend was observed in MW-22/22R (Figure 3-2) and MW-24/24R (Figure 3-3) in the vicinity. Also, as noted in the third annual report, both the pH and the oxygen reduction potential (ORP) values in several

wells within the plume have transformed to unfavorable levels indicating that the current remedial approach is ineffective at the site.

### 3.3.2 Indicator Parameters

Table 3-1 presents data of indicator parameters that serve as a reference to evaluate biodegradation potential of PCE over time. In reviewing the table, it is clear that the injection program was unable to maintain optimum pH (greater than 5), dissolved oxygen (DO) (less than 2 mg/L), and ORP (less than 0) levels that would favor reductive dechlorination. In a letter dated November 12, 2009, EPD recognized that the indicator parameters were unfavorable (EPD, 2009).

### 3.3.3 Statistical Analysis of PCE Trends

A Mann-Kendall test was performed on all monitoring wells to determine whether PCE concentrations were increasing or decreasing over time based on 80% and 90% levels of confidence. At both confidence levels, PCE was found to be decreasing or with no trend – indicating that the plume remained stable (ERM, 2010).

### 3.3.4 Plume Stability

Typically, dissolved contaminants tend to move with the groundwater flow. Considering that the groundwater seepage velocity is between 21 to 23 feet per year (CAP), it is interesting to note that the peak PCE plume illustrated in the sequential maps (Figure 2-9) has not migrated in the direction of ground water flow. The peak plume, therefore, appears to be stable and contained in the vicinity of Tanks 32 and 34.

## 3.4 FEASIBILITY OF CONTINUING THE CURRENT INJECTION PROGRAM

Based on the findings from Section 3.3, it appears that the current injection program is actually producing results that are counterproductive to bioremediation process. By contrast, as discussed in the aforementioned paragraph, the target contaminants had naturally attenuated prior to ERM's injection events. It is unclear whether the aerobic or anaerobic processes were the dominant attenuation force at the site. Even if the right environment is identified, lack of technology to deliver injected material to targeted zones presents significant challenges in enhanced attenuation. Nonetheless, attempts to create anaerobic environments when the subsurface is more conducive to aerobic environments and vice-versa lead to unexpected results.

In reviewing the comment letters in response to various progress reports prepared by the current site engineer, it is apparent that EPD has also raised numerous concerns about the effectiveness of the current remedial approach. Consequently, VOPAK does not recognize value in staying the current course for the next 20 years. VOPAK therefore recommends termination of the current injection program.

## 3.5 FEASIBILITY OF USING CHEMICAL OXIDATION AS AN ALTERNATIVE

Referring to Appendix I of the CAP, it is apparent that the 2001 chemical oxidation treatability study, was unable to demonstrate whether chemical oxidation would be successful at the site, due to certain sample preparation errors (ERM 2005). Furthermore, potassium permanganate can potentially sterilize the subsurface thereby retarding the natural bioremediation mechanisms that have been historically demonstrated at the site. In a letter dated February 13, 2004, EPD concurs that chemical oxidation is counterproductive to bioremediation (EPD, 2004). Consequently, VOPAK has developed a proposed action as outlined in Section 4.

SECTION 4

# 4 PROPOSED ACTION

Clearly, VOPAK has remediated all soil contamination that exceeded the RRS. Considering that the mass source material was removed in the form of soil excavation, the dissolved contamination in the groundwater is the primary media to be addressed. Also, based on VOPAK's evaluation (Section 3.3.1), natural attenuation had reduced the target contaminant levels in the groundwater at PAN-MW-9 by as much as 99%. After the injection program was initiated, however, the levels fluctuated to the extent that the PCE level rose to 1,900 ppb, reversing the decreasing trend. In addition, the current CAP requires VOPAK to meet the most stringent drinking water standards, which places an undue burden for an industrial site. It is therefore clear that an alternative course of action is necessary to address the prevailing groundwater contamination.

## 4.1 REMEDIAL STRATEGY

The prevailing enhance attenuation-based remedial program, involving chemical injection for reductive dechlorination, has been only partially successful. It appears that the primary impediment was lack of definition on whether aerobic, anaerobic, or facultative anaerobes were the driving forces in attenuating the COCs at the site. According to EPD, anaerobic enhancements have been ineffective in the coastal plain areas of Georgia (EPD, 2005). It is also possible that chemical amendments were unsustainable.

As evidenced by historic PCE degradation, in-situ bioremediation, and natural attenuation of CVOCs was apparent prior to the chemical injection events used for enhanced bioremediation. Additionally, the groundwater plume appears to be stable and contained. Similarly, VOPAK, therefore, believes that monitored natural attenuation (MNA) would be the most practical and cost-effective remedial strategy. VOPAK will utilize certain performance metrics to verify the effectiveness of MNA as the best remedial strategy. If the CVOC trends indicate an unacceptable time frame to reach remedial end points, during MNA implementation, VOPAK will implement contingency measures.

## 4.2 PROPOSED ACTION

The VRP encourages cost-effective allocation of limited resources to meet remedial objectives. In accordance with these objectives, VOPAK has developed the following conceptual remedial strategy.

1. Terminate the current injection program.
2. Perform a site-wide groundwater sampling event for COC analysis from wells located both within the PCE foot-print as well as wells located to the west that were historically used for BTEX monitoring.
3. Utilizing MNA as an interim remedial program, monitor the groundwater contaminants for a period of two years to reestablish the natural attenuation that was well in progress prior to injection activities.
4. In concurrence with EPD, VOPAK will select a fate and transport model to evaluate the effectiveness of the MNA program and compliance with site-specific RRS.
5. Based on the observed trends, VOPAK can make further decisions to continue with natural attenuation to reach remedial end points or utilize other enhanced techniques.
6. If enhancement is required, VOPAK will develop a microcosm test to evaluate the role of facultative anaerobes or other limiting factors. VOPAK can then implement alternative techniques to reach remedial end points within a period of 3 to 5 years as mandated by the EPD.

## 4.3 PERFORMANCE METRICS

To determine the effectiveness of the selected remedy, VOPAK will periodically perform a two-dimensional concentration/time analysis of the data from MNA monitoring and indicator parameters to address the following performance metrics:

- Is the plume stable or shrinking?
- Is the contaminant flux meeting remedial goals and is sustainable?
- Is the prevailing remedy cost-effective?
- What is the projected time frame to reach remedial end points?

### 4.3.1 MNA Monitoring

Wells within the contaminant plume will be utilized for MNA monitoring during the course of the VRP. These include wells currently utilized for MNA (MW-17/17R, MW-18/18R, PAN-MW-9, and MW-22/22R) and "performance monitoring wells" that include shallow wells PAN-MW-10, MW-16, MW-19, MW-23, MW-24/24R, MW-25, MW-26/26R, MW-27, and deep well MW-15. The deep monitor well MW-14 and shallow monitoring wells MW-20, MW-21, and MW-28, previously utilized for monitoring purposes, were determined to be "no longer present" based on a recent well inventory. As such, VOPAK will repair/re-drill monitoring wells MW-20, MW-21, and MW-28 for MNA/performance monitoring. Existing monitoring wells LAW-PZ-8 and MW-29,

previously not utilized, will be added for MNA/performance monitoring. Samples will be analyzed for VOCs and CVOCs. MNA sampling will be conducted as follows:

1. Samples will be collected from the wells on a quarterly basis.

2. Samples will be collected utilizing established low-flow sampling techniques.

### 4.3.2 Indicator Parameters

In addition to CVOC trend analysis, other indicator parameters such as pH, DO, ORP, and other inorganic parameters serve as important metrics in determining the change in site conditions and the effectiveness of the MNA program. Typically, data obtained from down-hole monitoring devices provide greater accuracy in defining such parameters than those obtained from traditional grab samples. As such, VOPAK plans to utilize down-hole data-logger devices in at least two wells to collect data on temperature, pH, DO, ORP, and conductivity. Because down-hole data loggers are greater than 1 inch in diameter, wells that are at least 2-inches in diameter are required. As such, VOPAK has selected PAN MW-9 (located within the plume) as a primary well and PAN MW-10 (located outside the plume) as a control well.

### 4.3.3 Fate and Transport Model

A two-dimensional analysis of contaminant trends and indicator parameters trends will be used to demonstrate whether the site is meeting the performance metrics. In addition, VOPAK will utilize a three-dimensional fate and transport model to evaluate the effect of dispersion, advection, sorption, and biodegradation. If the analysis is insufficient in addressing the performance metrics, VOPAK will consider statistical analysis to determine the performance metrics. If these tools indicate that the prevailing remedial strategy is unable to meet the performance metrics, contingency tasks will be initiated to develop an appropriate remedy.

### 4.3.4 Supplemental Data

After the horizontal and vertical delineation of the dissolved COCs is complete, VOPAK will consider collecting supplemental data from compound specific isotope analysis (CSIA), enzyme activity probes (EAP), or down-hole implants to demonstrate multiple lines of evidence on rates of degradation.

## 4.4 CONTINGENCY PLANNING

Since the groundwater contaminant plume is relatively stable, it appears that bioremediation may be a dominant natural attenuation mechanism at the site. If the performance metrics indicate that in-situ bioremediation alone is unable to attenuate the dissolved CVOCs, within a reasonable time frame, VOPAK will conduct a microcosm test to verify if enhancement is feasible. If enhancement is unfeasible and the contaminant plume is expanding beyond the point of demonstration, VOPAK will develop an alternative remedial strategy for EPD's approval.

## 4.5 UPDATED RRS

During the preparation of the VRP application, VOPAK computed Type 4 risk RRSs for groundwater based on non-residential properties using EPA's Risk Assessment Guidance for Superfund (RAGS) equations 1 and 2, in conformance with Georgia EPD Rule 391-3-19. In calculating RRS, VOPAK utilized the current COC associated with the PCE release and the latest regional screening level values (RSL) data published by the U.S. Environmental Protection Agency (EPA) in May 2010.

Table 4-1 presents the revised Type 4 RRS values and compares them with the current RRS values for both CVOCs and aromatic hydrocarbons based on the latest toxicity factors. Tables 4-2 through 4-5 include backup computations used in developing the revised Type 4 RRS values listed in Table 4-1. The revised RRS values will be used as groundwater standards in this VRP.

## 4.6 PROJECT CLOSURE

Upon completion of remedial activities, VOPAK will submit to the EPD a CSR establishing that the remedial endpoint was reached as per the VRP, and certify that the property is in compliance with the remedial standards. VOPAK understands that, at any time before the CSR is submitted, the EPD can terminate VOPAK's enrollment in the VRP, if the EPD determines that VOPAK failed to properly follow the Voluntary Remediation Plan requirements, or, that continued enrollment will lead to an "imminent or substantial danger to human health and the environment." If the EPD determines that the CSR is compliant with the "provisions, purposes, standards, and policies" of the VRP, the EPD will deem the site to be compliant with groundwater RRS.

SECTION 5

# 5 PROJECTED SCHEDULE

To accomplish the proposed corrective action tasks, EIC has developed a 4-Step milestone schedule. Figure 5-1 presents a Gantt Chart for VOPAK's Projected Milestone Schedule.

## 5.1 STEP 1 – MNA CALIBRATION

Within the first 12 months of participation in the program, VOPAK will conduct the following:

- Referring to the COCs, listed in Table 1-2, complete horizontal delineation of all COCs within the site during the first 12 months. Also conduct vertical delineation within 30 months. Based on historic data, off-site delineation is not required.
- Update all relevant Tables and Figures from CAP Annual Report with the most current data.
- Re-evaluate RRS values, based on site-specific risk factors.
- Conduct an investigation to identify the source(s) of BTEX contamination.
- Using down-hole data loggers evaluate the tidal and meteorological effects on groundwater levels in on-site wells.
- Using down-hole monitoring instrument collect in situ data on indicator parameters.
- Conduct Monitored Natural Attenuation sampling
- Analyze data collected, determine trends, refine horizontal and vertical delineation of the contaminant plume, and prepare reports to determine the most effective strategy for VOPAK to reach its remedial goals within a three to five year timeframe.
- Rehabilitate selected missing or damaged wells.
- Submit reports to the EPD following the VRP reporting requirements and the Projected Milestone Schedule.

## 5.2 STEP 2 – MNA TREND ANALYSIS

Within the first 24 months of participation in the program, VOPAK will conduct the following:

- Utilizing the MNA monitoring data, evaluate trends to determine if the CVOCs are progressively reducing such that the RRS will be met in a reasonable time frame.
- In concurrence with EPD, select a fate and transport model to evaluate compliance with site-specific RRS.
- If the site data concludes that MNA would be unable to reach remedial end points within the projected 60-month time schedule, implement contingency remedy.

## 5.3 STEP 3 – MNA CONFIRMATION

Within the first 30 months of participation in the program, VOPAK will conduct the following:

- Update the site conceptual model with information gained in Steps 1 and 2.
- If MNA appears unfeasible in meeting projected remedial goals, conduct a microcosm test to determine enhancements to increase the biodegradation potential of CVOCs. The results of the microcosm test may also lead to other alternative remedial technologies to reach remedial end points.
- Finalize the remediation plan.
- Provide a preliminary cost estimate for implementing remediation and associated tasks

## 5.4 STEP 4 - VRP CLOSURE

Within the first 60 months of participation in the program, VOPAK will conduct the following:

- Submit a CSR with mandatory certifications.
- Post-closure monitoring program.

Value exceeds a risk reduction standard
NR = not reported by the lab
NS = not sampled
NI = not installed
< = less than indicated value 0.950054289
< 5/< 500 = sample was analyzed twice
J this is an estimated value that is above the method detection limit but below the practical quantitation limit.
The sample denoted MW-10 on 12/18/98 is believed to have been collected from MW-9, I.e. the two samples were mislabeled. This table shows what is believed to be correct.
Risk reduction standard, the higher of the Type 3 or 4 from Table 2 of Risk Reduction Standards dated August 13, 2001
LAW-PZ-8 was found damaged during June 2006 sampling event and was not sampled. It was replaced by LAW-PZ-8R on 10/9/2006.
MW-17 was replaced by MW-17R on 10/10/2006.
MW-26 was replaced by MW-26R on 10/9/2006.

Value exceeds a risk reduction standard
NR = not reported by the lab
NS = not sampled
NI = not installed
< = less than indicated value 0.950054289
< 5/< 500 = sample was analyzed twice
J this is an estimated value that is above the method detection limit but below the practical quantitation limit.
The sample denoted MW-10 on 12/18/98 is believed to have been collected from MW-9, I.e. the two samples were mislabeled. This table shows what is believed to be correct.
Risk reduction standard, the higher of the Type 3 or 4 from Table 2 of Risk Reduction Standards dated August 13, 2001
LAW-PZ-8 was found damaged during June 2006 sampling event and was not sampled. It was replaced by LAW-PZ-8R on 10/9/2006.
MW-17 was replaced by MW-17R on 10/10/2006.
MW-26 was replaced by MW-26R on 10/9/2006.

NS = Not sampled
J = Lab estimated value
*F35 = Lab estimated value
NVD = Color indicating field test for dissolved iron was used, but color was Not Visually Detected (NVD)
LAW-PZ-8 was found damaged during June 2006 sampling event and was not sampled. It was replaced by LAW-PZ-8R on 10/9/2006.
MW-17 was replaced by MW-17R on 10/10/2006.
MW-26 was replaced by MW-26R on 10/9/2006.

## Table 4-1: Comparison of CAP RRS for Groundwater to Revised Type 4 RRS

| Constituents | CAS No. | Current CAP RRS (µg/L) | Revised Type 4 RRS from Table 2-2 (µg/L) |
|---|---|---|---|
| Tetrachloroethene (PCE) | 127-18-4 | 5 | 5 |
| Trichloroethene (TCE) | 79-01-6 | 5 | 38 |
| 1,2-Dichloroethene (cis) | 156-59-2 | 1,020 | 1,022 |
| Vinyl chloride | 75-01-4 | 2 | 3 |
| | | | |
| Benzene | 71-43-2 | 15 | 9 |
| Ethylbenzene | 100-41-4 | 3,750 | 700 |
| Toluene | 108-88-3 | 2,030 | 5,241 |
| | 133-02-07 | 10,000 | 10,000 |

## Table 4-2: Type 4 Risk Reduction Standards for Groundwater [Rule 391-3-19-.07(9)(c)]

| Constituents (mg/L) | CAS No. | RAGS (Equation 2 from Table 2-3) Non-Carcinogenic Adult | RAGS (Equation 1 from Table 2-4) Carcinogenic Adult | Lesser of values from Equations 1 and 2 | Table 1, App III or Background, or Detection Limit (from GA EPD 391-3-19) | Type 4 RRS (lesser of values from Equations 1 and 2) |
|---|---|---|---|---|---|---|
| Tetrachloroethene (PCE) | 127-18-4 | 4.45E-01 | 3.83E-03 | 3.83E-03 | 5.00E-03 | 5.00E-03 |
| Trichloroethene (TCE) | 79-01-6 | NC | 3.77E-02 | 3.77E-02 | 5.00E-03 | 3.77E-02 |
| 1,2-Dichloroethene (cis) | 156-59-2 | 1.02E+00 | NC | 1.02E+00 | 7.00E-02 | 1.02E+00 |
| Vinyl chloride | 75-01-4 | 1.50E-01 | 3.27E-03 | 3.27E-03 | 2.00E-03 | 3.27E-03 |
| | | | | | | |
| Benzene | 71-43-2 | 7.21E-02 | 8.72E-03 | 8.72E-03 | 5.00E-03 | 8.72E-03 |
| Ethylbenzene | 100-41-4 | 2.27E+00 | 2.91E-02 | 2.91E-02 | 7.00E-01 | 7.00E-01 |
| Toluene | 108-88-3 | 5.24E+00 | NC | 5.24E+00 | 1.00E+00 | 5.24E+00 |
| | 133-02-07 | 2.88E-01 | NC | 2.88E-01 | 1.00E+01 | 1.00E+01 |

**Notes:**

*According to the EPA's Calculation of Risk-based PRG's, if a parameter is not defined for a contaminant, it should be given a zero value (RAGS Vol 1., EPA, 1991). A value of "NC" was assigned when both parameters were not defined, due to the inability to divide an equation by zero.

## Table 4-3: Type 4 Non-Carcinogenic Evaluation for Groundwater; Non-Residential Adult (RAGS Equation 2)

| Constituents | CAS No. | THI | BW (kg) | AT (yr) | CF (d/yr) | EF (d/yr) | ED (yr) | Irw (L/d) | RfDo (mg/kg-d) | Ira ($m^3$/d) | K ($L/m^{3)}$ | RfDi (from Table 2-5) (mg/kg-d) | RAGS (Equation 2) Non-Carcinogenic Adult (mg/L) |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Tetrachloroethene (PCE) | 127-18-4 | 1 | 70 | 25 | 365 | 250 | 25 | 1 | 1.00E-02 | 20 | 0.50 | 7.71E-02 | 4.45E-01 |

| | 133-02-07 | 1 | 70 | 25 | 365 | 250 | 25 | 1 | 2.00E-01 | 20 | 0.50 | 2.86E-02 | 2.88E-01 |

**Notes:**

Pursuant to Rule 391-3-19-.07(7)(b)1, groundwater RRS are calculated to evaluate the potential for noncancer toxic effects via ingestion of, or inhalation of volatiles from, groundwater. The water-air concentration relationship is applicable only to constituents with a Henry's Law constant of greater than 1 x 10 atm-m /mole and a molecular weight of less than 200 g/mole (RAGS Part B, EPA, 1991).

*According to the EPA's Calculation of Risk-based PRG's, if a parameter is not defined for a contaminant, it should be given a zero value (RAGS Vol 1., EPA, 1991). A value of 'NC' was assigned when both parameters were not defined, due to the inability to divide an equation by zero.

kg = kilogram; yr = year; d/yr = days per year; L/d = liters per day; kg/mg = kilograms per milligram; mg/kg-d = milligram per kilogram day; m3/d =cubic meters per day;
L/m3 = liters per cubic meter; mg/L = milligrams per liter
THI = Target hazard index
BW = Adult body weight
AT = Averaging Time
CF = Conversion Factor
EF = Exposure Frequency
ED = Exposure Duration
IRw = Daily water ingestion rate
RfDo = Oral chronic reference dose
IRa = Daily inhalation rate of air
K = Water-to-air volatilization factor
RfDi = Inhalation chronic reference dose

## Table 4-4: Type 4 Carcinogenic Evaluation for Groundwater; Non-Residential Adult (RAGS Equation 1)

| Constituents | CAS No. | TR | BW (kg) | AT (yr) | CF (d/yr) | EF (d/yr) | ED (yr) | IRw (L/d) | SFo $(mg/kg\text{-}d)^{-1}$ | IRa (m3/d) | K $(L/m^3)$ | SFi (from Table 2-5) $(mg/kg\text{-}d)^{-1}$ | RAGS (Equation 1) Carcinogenic Adult (mg/L) |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Tetrachloroethene (PCE) | 127-18-4 | 1.00E-05 | 70 | 70 | 365 | 250 | 25 | 1 | 5.40E-01 | 20 | 0.5 | 2.07E-02 | 3.83E-03 |

**Notes:**

Pursuant to Rule 391-3-19-.07(7)(b)1, groundwater RRS are calculated to evaluate the potential for noncancer toxic effects via ingestion of, or inhalation of volatiles from, groundwater. The water-air concentration relationship is applicable only to constituents with a Henry's Law constant of greater than 1 x 10 atm-m /mole and a molecular weight of less than 200 g/mole (RAGS Part B, EPA, 1991).

*According to the EPA's Calculation of Risk-based PRG's, if a parameter is not defined for a contaminant, it should be given a zero value (RAGS Vol 1., EPA, 1991). A value of 'NC' was assigned when both parameters were not defined, due to the inability to divide an equation by zero.

kg = kilogram; yr = year; d/yr = days per year; L/d = liters per day; kg/mg = kilograms per milligram; mg/kg-d = milligram per kilogram day; m3/d =cubic meters per day;
L/m3 = liters per cubic meter; mg/L = milligrams per liter
TR = Target excess individual lifetime cancer risk
BW = Adult body weight
AT = Averaging Time
CF = Conversion Factor
EF = Exposure Frequency
ED = Exposure Duration
IRw = Daily water ingestion rate
SFo = Oral cancer slope factor
IRa = Daily inhalation rate of air
K = Water-to-air volatilization factor
SFi = Inhalation cancer slope factor

## Table 4-5: Toxicity Factors

| Constituents | CAS No. | Non-Carcinogenic | | Carcinogenic | |
|---|---|---|---|---|---|
| | | RfCi[*1] | RfDi[*2] | IUR[*1] | SFi[*2] |
| Tetrachloroethene (PCE) | 127-18-4 | 2.70E-01 | 7.71E-02 | 5.90E-06 | 2.07E-02 |
| Trichloroethene (TCE) | 79-01-6 | 0 | 0 | 2.00E-06 | 7.00E-03 |
| 1,2-Dichloroethene (cis) | 156-59-2 | 0 | 0 | 0 | 0 |
| Vinyl chloride | 75-01-4 | 1.00E-01 | 2.86E-02 | 4.40E-06 | 1.54E-02 |
| | | | | | |
| Benzene | 71-43-2 | 3.00E-02 | 8.57E-03 | 7.80E-06 | 2.73E-02 |
| Ethylbenzene | 100-41-4 | 1.00E+00 | 2.86E-01 | 2.50E-06 | 8.75E-03 |
| | 108-88-3 | 5.00E+00 | 1.43E+00 | 0 | 0 |
| Xylenes (total) | 133-02-07 | 1.00E-01 | 2.86E-02 | 0 | 0 |

**Notes:**

*According to the EPA's Calculation of Risk-based PRG's, if a parameter is not defined for a contaminant, it should be given a zero value (RAGS Vol 1., EPA, 1991).

[*1] May 2010 Regional Screening Level (RSL) Summary Table data from EPA.

[*2] Calculated using "Conversion Equations for Inhalation Reference Concentrations and Inhalation Unit Risk Factors" from EPD, Georgia Dept of Natural Resources: Compliance Status Report 391-3-19-.07 (Cited 22 April, 2010).

RfCi = Chronic inhalation reference concentration
RfDi = Inhalation chronic reference dose
IUR = Chronic inhalation unit risk
SFi = Inhalation cancer slope factor

## APPLICANT'S CERTIFICATION

In order to be considered a qualifying property for the VRP:

(1) The property must have a release of regulated substances into the environment;
(2) The property shall not be:
- (A) Listed on the federal National Priorities List pursuant to the federal Comprehensive Environmental Response, Compensation, and Liability Act, 42 U.S.C. Section 9601.
- (B) Currently undergoing response activities required by an order of the regional administrator of the federal Environmental Protection Agency; or
- (C) A facility required to have a permit under Code Section 12-8-66.

(3) Qualifying the property under this part would not violate the terms and conditions under which the division operates and administers remedial programs by delegation or similar authorization from the United States Environmental Protection Agency.
(4) Any lien filed under subsection (e) of Code Section 12-8-96 or subsection (b) of Code Section 12-13-12 against the property shall be satisfied or settled and released by the director pursuant to Code Section 12-8-94 or Code Section 12-13-6.

In order to be considered a participant under the VRP:
- (1) The participant must be the property owner of the voluntary remediation property or have express permission to enter another's property to perform corrective action.
- (2) The participant must not be in violation of any order, judgment, statute, rule, or regulation subject to the enforcement authority of the director.

I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations.

I also certify that this property is eligible for the Voluntary Remediation Program (VRP) as defined in Code Section 12-8-105 and I am eligible as a participant as defined in Code Section 12-8-106.

STATE OF GEORGIA
COUNTY OF FULTON

WHEREAS, on the 15th day of December, 1948, the STATE OF GEORGIA by quitclaim deed acquired from the UNITED STATES OF AMERICA, acting by and through its WAR ASSETS ADMINISTRATOR, title to a certain tract of land lying and being in the County of Chatham, State of Georgia, containing 407.59 acres, more or less, and known as the Medical Depot site in Chatham County, Georgia, adjacent to the Savannah River; said quitclaim deed being recorded in Record Book 48-F, Folio 272, in the Office of the Clerk of the Superior Court, Chatham County, Georgia, and at page 101 of Deeds to State Property book in the office of the Secretary of State of Georgia; and

WHEREAS, by section 4 of Act No. 174 (Senate Bill No. 55), approved by the Governor on February 17, 1949, the 1949 Session of the General Assembly authorized the Governor to convey for and in behalf of the State title to lands and improvements known as the Medical Depot site in Chatham County, Georgia, adjacent to the Savannah River, to the Georgia Ports Authority upon payment of such nominal sum to the State Treasurer as may be agreed upon by the Governor and the Authority.

NOW, THEREFORE, In consideration of the sum of $1000.00 (One Thousand) Dollars and for other valuable considerations paid to the Treasurer of the State of Georgia, as provided and in accordance with said Act No. 174, I, HERMAN TALMADGE, GOVERNOR OF THE STATE OF GEORGIA, and for and in behalf of the STATE OF GEORGIA, have bargained, sold and conveyed, and do by these presents bargain, sell, convey, remise, release, and forever quitclaim unto the GEORGIA PORTS AUTHORITY, its successors and assigns, all the right, title, interest, claim or demand which the State of Georgia has or may have had in or to the following described property, situate, lying and being in the County of Chatham, State of Georgia to wit:

ALL those tracts or parcels of land lying and being in Chatham County, Georgia containing 430.09 acres, being more particularly described as follows:

PARCEL NO. 1- Beginning at an iron pipe at the intersection of the Northern right-of-way of Brampton Road and the Eastern right-of-way line of the Savannah and Atlanta Railroad; thence with Eastern right-of-way of the Savannah and Atlanta Railroad North 26 deg. 25 min. 41 sec. West, 700.00 feet to a point; thence North 56 deg. 07 min. 37 sec. East 40.0 feet to a point on the Eastern right-of-way line of a railroad spur of the Savannah Warehouse and Compress Company; thence Northerly along curvature of said right-of-way line to a point which is North 03 deg. 45 min. 01 sec. West, 282.52 feet from the immediately preceding point; thence continue Northerly along the curvature of said right-of-way line to a point which is North 04 deg. 55 min. 24 sec. East, 267.99 feet from the immediately preceding point; thence Southerly along the curvature of the Western right-of-way line of another railroad spur of the Savannah Warehouse and Compress Company to a point which is South 51 deg. 11 min. 19 sec. East 236.14 feet from the immediately preceding point; thence continue Southerly along the curvature of said Western right-of-way line to a point which is South 33 deg. 07 min. 28 sec. East 227.81 feet from the immediately preceding point; thence North 56 deg. 07 min. 37 sec. East 49.7 feet to a point on the Eastern right-of-way line of railroad spur of the Savannah Warehouse and Compress Company; thence Northerly along the

curvature of said Eastern right-of-way to a point which is North 31 deg. 41 min. 49 sec. West, 215.5 feet from the immediately preceding point; thence continue Northerly along curvature of said right-of-way line to a point which is North 47 deg. 59 min, 35 sec. West, 275.9 feet from the immediately preceding point; thence continue Northerly along the curvature of said right-of-way line to a point which is North 21 deg. 20 min. 30 sec. West, 331.8 feet from the immediately preceding point; thence continue Northerly along the curvature of said right-of-way line to a point which is North 2 deg. 49 min. 14 sec. East 173.3 feet from the immediately preceding point; thence North 30 deg. 10 min. East 360.1 feet to a point; thence North 59 deg. 50 min. West, 76.0 feet to a point; thence South 44 deg. 48 min. 58 sec. West, 94.8 feet to a point; thence North 10 deg. 17 min. 14 sec. East, 928.8 feet to a pipe; thence North 06 deg. 09 min, 12 sec. East 2074.4 feet to a railroad iron; thence North 01 deg. 00 min. 48 sec. West, 900.0 feet to a point in center line of Pipemakers Canal; thence Easterly with the center line of said canal to a point on the low water line of the Western bank of Savannah River, said point being North 68 deg. 24 min. 47 sec. East 2945.1 feet from the immediately preceding point; thence Southerly 4300 feet along the low water line of Savannah River to a point which is South 27 deg.25 min. 50 sec. East 4238.0 feet from the immediately preceding point; thence South 56 deg. 07 min. 37 sec. West 3700.0 feet along the Northerly line of Brampton Road to the point of beginning, containing 426.25 acres, more or less.

PARCEL NO. 2- Commencing at an iron pipe at the intersection of the Northern right-of-way line of Brampton Road and the Eastern right-of-way line of the Savannah and Atlanta Railroad; thence North 26 deg. 25 min. 41 sec. West 765.0 feet to the point of beginning of herein described parcel; thence North 26 deg. 25 min. 41 sec. West 485.0 feet along the Eastern right of way line of the Savannah and Atlanta Railroad; thence Northerly along the curvature of the Eastern right of way line of the Chatham Terminal Company to a point which is North 06 deg. 13 min. 54 sec. East 335.8 feet from immediately preceding point; thence North 30 deg. 12 min. 20 sec. East 185.0 feet along the Southeastern right-of-way of the East track of Savannah Warehouse and Compress Company; thence Southerly along the curvature of the Western right-of-way line of a spur track of the Savannah Warehouse and Compress Company to a point which is South 13 deg. 15 min. 03 sec. East 318.5 feet from immediately preceding point; thence continuing Southerly along the curvature of said Western right-of-way line to a point which is South 05 deg. 31 min. 39 sec. East 280.3 feet from immediately preceding point; thence continuing Southerly along the curvature of said Western right-of-way line to the point of beginning, which is South 02 deg. 18 min. 27 sec. West 339.3 feet from immediately preceding point.

The above described tract is Lot 8 of the Industrial Subdivision of Savannah Warehouse and Compress Company and contains 2.78 acres, more or less.

PARCEL NO. 3- A certain tract or parcel of land, lying and being in Chatham County, Georgia, being more particularly described as follows:

Beginning at the intersection of the Eastern right-of-way line of U. S. Highway No. 17 and the Northern right-of-way line of the Savannah Warehouse and Compress Company's East track; thence North 06 deg. 05 min. 50 sec. East 442.5 feet along said Eastern right-of-way line of U. S. Highway No. 17; thence Easterly along the curvature of the Southern right-of-way line of the Savannah and Atlanta Railroad spur to the Savannah Warehouse and Compress Company to a point which is North 71 deg. 10 min. 55 sec. East 275.6 feet from immediately preceding point; thence South 30 deg. 12 min. 20 sec. West 612.0 feet along the Northern right-of-way line of the Savannah Warehouse and Compress Company's East tract to the point of beginning, containing 1.06 acres, more or less.

The above described parcel is Lot 7 of Industrial Subdivision of Savannah Warehouse & Compress Company.

Exception from said above described land the following described land and buildings,

to-wit:

A tract or parcel of land, situate and being in the County of Chatham, State of Georgia, being a portion of the Savannah Quartermaster Depot, and a portion of the tract of land formerly owned by the Savannah Warehouse and Compress Company, and containing 22.50 acres, more or less, being more particularly described as follows:

Beginning at a point at the intersection of center line of Rethers Street with line parallel to and 25 feet southerly from the southerly line of Building 3 (A-G); thence South 68 deg. 25 min. West, 1870 feet along the A.C.L. Railroad Spur to a point on a fence line West of Tomochichi Road; thence North 13 deg. 52 min. East 724 feet along the aforementioned fence line; thence North 68 deg. 25 min. East, 1450 feet along same fence line to the intersection of centerline of Rethers Street; thence South 21 deg. 35 min. East 590 feet along the centerline of Rethers Street to the point of beginning.

Buildings 49-B with adjacent wharf, containing 21,030 sq. ft., more or less, being more particularly described as follows:

Beginning at the intersection of Hart Street with the Southwest corner of Bldg. 49-B and approximately 10 feet southerly from the Southerly line of railroad spur; thence North 68 deg. 25 min. East 140 feet; thence South 17 deg. 58 min. East 160 feet; thence South 72 deg. 30 min. West 130 feet; thence North 21 deg. 35 min. West 151 feet to the point of beginning.

All bearings and distances are scaled from map of the U. S. Engineer Office, Savannah, Georgia, Drawing No. QMDS-1/702.

Buildings No. 1 (A-E inclusive), Building No. 3 (A-G inclusive) and Bldg. No. 49 with adjacent wharf are located on the aread described herein.

Together with all the personal property acquired and retained by the State of Georgia from the United States pursuant to and under the terms of the aforesaid quitclaim deed from the United States to the State of Georgia which quitclaim deed appears of record, as hereinbefore set out, in Record Book 48-F, Folio 272, in the office of the Clerk of the Superior Court of Chatham County, Georgia, the said personal property being listed in Schedule "A" attached to and made a part of the aforesaid quitclaim deed from the United States to the State of Georgia.

All said property, both real and personal, being the same property acquired by the State of Georgia from the United States of America, acting by and through its War Assets Administrator, by quitclaim deed which appears of record in Record Book 48-F, Folio 272, in the office of the Clerk of the Superior Court of Chatham County, Georgia, together with all the rights, members, and appurtenances to the said described premises in anywise appertaining or belonging, but for the following exceptions, which exceptions are the same as those contained in said deed from the United States of America to the State of Georgia, and are, to wit:

1. An Easement in favor of the City of Savannah, Georgia, to dig and excavate part of the land east of Pipemakers Creek.

2. Rights and Easements of railroad companies under an agreement dated October 20, 1916, as amended by an agreement dated June 24, 1942.

3. Outstanding rights of railroad companies under the railroad storage yard agreement dated November 17, 1919, as amended by agreement dated June 24, 1942.

4. Outstanding rights under an agreement dated September 25, 1925, as amended by agreement dated June 24, 1942.

5. Rights of Lindsay McMillan Company, or its successors and assigns, under an agreement in connection with the deed dated April 9, 1928.

6. All existing easements for public roads, highways, public utilities, railroads and pipelines.

7. All outstanding rights of third persons in and to that part of the land within Pipemakers Creek or Canal.

8. Joint use by the Department of the Army with party of the second part of Gibbins Road from entrance gate on Highway No. 17 to Tomochichi Road, thence to building 3-A; primary electric line from existing sub-station; existing water distribution system; existing sewer lines down Livingston Street to Savannah River; Rae's Hall Road around North side of requested area to Hart Street, to building No. 49-B, with adjacent wharf.

9. Easement from United States of America to Mayor and Aldermen of the City of Savannah dated July 16, 1948, for a water pipeline fifty (50) feet wide across the property hereinbefore described.

10. Any other outstanding rights appearing of record.

11. And further excepting from this conveyance certain mineral rights which have been reserved by the United States of America in accordance with Executive Order 9908, approved December 5, 1947, (12 F. R. 8223), being all uranium, thorium, and all other materials determined pursuant to section 5 (b) (1) of the Atomic Energy Act of 1946 (60 Stat. 761) to be peculiarly essential to the production of fissionable material, contained, in whatever concentration, in deposits in the lands covered by this instrument, which are hereby reserved for the use of the United States, together with the right of the United States through its authorized agents or representatives at any time to enter upon the land and prospect for, mine, and remove the same, making just compensation for any damage or injury occasioned thereby. However, such land may be used, and any rights otherwise acquired by this disposition may be exercised, as if no reservation of such materials had been made; except that, when such use results in the extraction of any such material from the land in quantities which may not be transferred or delivered without a license under the Atomic Energy Act of 1946, as it now exists or may hereafter be amended, such material shall be the property of the United States Atomic Energy Commission, and the Commission may require delivery of such material to it by any possessor thereof after such material has been separated as such from the ores in which it was contained. If the Commission requires the delivery of such material to it, it shall pay to the person mining or extracting the same, or to such other person as the Commission determines to be entitled thereto, such sums, including profits, as the Commission deems fair and reasonable for the discovery, mining, development, production, extraction, and other services performed with respect to such material prior to such delivery, but such payment shall not include any amount on account of the value of such material before removal from its place of deposit in nature. If the Commission does not require delivery of such material to it, the reservation hereby made shall be of no further force or effect.

TO HAVE AND TO HOLD the said described premises unto the GEORGIA PORTS AUTHORITY, its successors and assigns, so that neither the STATE OF GEORGIA nor its assigns, nor any person or persons claiming under it shall at any time claim or demand any right, title, or interest to the described premises or its appurtenances.

IN WITNESS WHEREOF, I have hereunto set my hand and affixed the seal of the State of Georgia this the 29 day of March, 1949.

Signed, sealed and delivered
in the presence of:
Gladys Creal
Notary Public, Georgia, State at Large.
My commission Expires Jan. 9, 1950

# SUMMARY OF HISTORIC BTEX INVESTIGATIONS

# SUMMARY OF HISTORIC BTEX INVESTIGATIONS

In reviewing site-wide total BTEX concentration isopleth maps and groundwater elevation contour maps in various environmental reports by Law, ERM, and WPC since 1996, EIC has determined that three well-defined dissolved BTEX contaminant source plumes have existed at the site since at least 1996 and continue to exist at present. Two of the plumes have historically been located at the western end of the largest tank farm, designated as the Number 1 Tank Farm (Exhibit 1). A third plume has historically been located within the relatively smaller Number 2 Tank Farm where a PCE plume also exists. Based on the ERM and WPC reports, the LNAPL and BTEX plumes on the western side of the site are currently being addressed under the Watershed Protection program of the GA EPD, while the eastern PCE and BTEX contaminant plumes were being addressed under the HSRA program of the GA EPD. Following are EIC's findings regarding potential migration of the BTEX from the western plumes to the location of the PCE plume.

## 1.0 BTEX Plumes Defined in 1996

Exhibit 1 (LAW, 1996) is a site-wide map that illustrates the location and horizontal extent of the three dissolved BTEX plumes in groundwater on June 12, 1996. The first plume is located within the same foot-print as the PCE plume addressed in the VRP. The second and third BTEX plumes are located on the western end of the site near AST 20 and ASTs 15/22, respectively, of the Number 1 Tank Farm west of Turner Street. From Exhibit 1 it is apparent that the first plume was located within the same foot-print as the current PCE plume. The second BTEX plume, located to the west of the first plume, was separated by a distance of more than 1,000 feet. A smaller third BTEX plume was located approximately 400 feet to the north west of the second plume. The sources of these plumes were not apparent from the available documents.

## 2.0 1999 Diesel Spill in the Number 1 Tank Farm Area

On January 12, 1999, a major diesel release took place from AST 22 that resulted in LPH accumulations at the second and third plumes. According to a historic report, the release discharged approximately 1 million gallons of diesel into the common containment berm surrounding ASTs 20, 21, and 22 (ERM, 1999). After recovery activities were completed, it was determined by ERM that 30,000 to 40,000 gallons of diesel had infiltrated into the soil. Since 1999, several remediation technologies have been applied in this area (first by ERM and then by WPC), in an attempt to remediate diesel LNAPL from the subsurface. According to a series of reports by WPC (all titled "Remediation Activities Report"), the Surfactant Enhanced Aquifer Remediation (SEAR) injection technique reportedly recovered "to date" "approximately 6,992 liquid/vapor equivalent gallons of free product from the subsurface" from 2008 to July 2010 (WPC, 2011). Prior to initiating this technique, 17 surfactant injection wells and 23 surfactant extraction wells were installed. According to this report and other WPC and ERM reports (EIC has reviewed regarding the diesel spill and remediation) a total of approximately 28,726 gallons of LNAPL appear to remain in the subsurface at present in the areas of ASTs 20 and 22, respectively.

## 3.0 Input of Area of Diesel Spill on BTEX Concentrations in Groundwater

After the diesel release occurred, however, by January 2006, the diesel product had accumulated within in the same general areas in the Number 1 Tank Farm as the BTEX plumes were present prior to the release. The diesel product plumes are illustrated in Exhibit 2 (ERM, 2006). Exhibit 3 (WPC, 2011) illustrates the western area of the Number 1 Tank Farm, including ASTs 20, 21, and 22, injection and extraction wells, and other wells. Exhibits 4 and 5 of the same report illustrate the extent of the diesel product plumes near ASTs 20 and 22, respectively, as of October 2010. The WPC reports, however, only addressed the progress of diesel product recovery in the Number 1 Tank Farm and did not address nor illustrate the dissolved BTEX constituents in groundwater associated with the plumes. Referring to Exhibit 6 (ERM, 2006), the BTEX constituent levels in January 2006 were below MDL in all the sampled wells except for two wells, PZ-3 and RW-6. At PZ-3, concentrations in groundwater of Benzene, Toluene, Ethyl-Benzene, and Xylene were 46, 5, 69, and 160 ug/L, respectively and at RW-6 only Ethyl-Benzene was detected at 3 ug/L. As such, it is likely that such relatively low BTEX concentrations would not act as a source for BTEX at the eastern BTEX plume located 1,000 feet away and side-gradient to the groundwater flow direction (as described in Section 4.0).

## 4.0 Potential for BTEX Plume Migration into the Number 2 Tank Farm Area

Referring to Exhibit 7 (Law, 1996), an east-west orientated groundwater divide is located across the western half of the site in the Number 1 Tank Farm from the vicinity of AST 20 to AST 6, where groundwater apparently flows to the north and to the south from the apex of the divide. The eastern extent of the divide terminates at Tank 6. From this exhibit, the water table slopes solely to the north in the eastern half of the site. Also, a groundwater surface topographic high exists in the south-central area of the site. Exhibit 8 (ERM, 2001) from the "February 8, 2001 First Quarterly Groundwater Quality Report" illustrates that the groundwater flow in the western side of the site within the Number 1 Tank Farm is primarily towards the northeast. The groundwater surface contours remained very similar in maps the following ERM quarterly reports from 2001 through 2003. Exhibit 9 (ERM, 2005) illustrates a topographic high to the east of the two western-most bermed areas of the Number 1 Tank Farm in 2004. Other quarterly ERM reports through January 2006 illustrate a similar topographic high feature in a series of ten groundwater elevation contour maps prepared, with the exception of one indicating a flow to the northeast. EIC believes that, due to the topographic barriers of the potentiometric surface therefore inhibit groundwater flow from the area of the western BTEX plumes towards the east. Consequently, BTEX contamination from the western plumes would not likely serve as a source for the eastern dissolved BTEX plume within the PCE foot-print.

Recent groundwater elevation contour maps in the area of the PCE plume for December 2008 and March 2009 that are depicted in Exhibit 10 and Exhibit 11, respectively (ERM, 2010) have indicated that the groundwater flow is from south-southwest to the north-northeast and not from the west. This is another indicator that the BTEX plumes on the west side of the site would not migrate side-gradient act as a source of BTEX in the PCE plume area. It is therefore possible that the sole source of BTEX in this area resulted from unknown source(s) within this area. It should be noted that EIC wasn't able to locate a recent site-wide groundwater elevation contour map, site-wide gauging data, nor site-wide groundwater sampling data to further investigate potential sources. As

part of the VRP, EIC has proposed a site-wide gauging/sampling event of selected wells to further evaluate the BTEX plumes.

## 5.0 Reduction in BTEX Plume Concentration at the Number 2 Tank Farm

Based on a comparison of four concentration maps of the individual BTEX constituents of Benzene, Toluene, Ethyl-Benzene, and Xylene shown in Figures 2-5, 2-6, 2-7, and 2-8, respectively (in the main body of the VRP application) that to the total BTEX map outlined in Exhibit 1 (Law, 1996), the concentration levels of BTEX have gradually diminished since 1996. Referring to Figure 2-8, the highest Xylene concentration of the current BTEX plume was 47,000 ug/L whereas the lowest Xylene concentration in 1996 (Exhibit 1), was 60,500 ug/L. This represents a 22 percent reduction in Xylene concentrations. During the VRP program, Vopak will further monitor the BTEX concentrations to determine whether the BTEX is naturally attenuating at the site.

**Re: Report on Fourth Quarter 2011 (Baseline) VIRP Quarterly Monitored Natural Attenuation (MNA) Ground Water Monitoring in CVOC/VOC Plumes, VOPAK Terminal Savannah Inc., Savannah, Georgia**

File: 390020

Dear Mr. Jones:

VOPAK Terminal Savannah, Inc. (VOPAK) retained Environmental International Corporation (EIC) to perform the first quarterly Monitored Natural Attenuation (MNA) groundwater sampling event during the fourth Quarter of 2011 from site wells since the approval of VOPAK's Voluntary Investigation and Remediation Plan (VIRP) submittal. In the GA EPD (EPD) August 31, 2011 VIRP approval letter addressed to VOPAK, the EPD specified "quarterly groundwater monitoring to evaluate [the potential for] MNA…" was required. The quarterly sampling events will continue under the VIRP program schedule or as required by the EPD.

The previous groundwater sampling event of record was conducted from April 26 to 27, 2010 by WPC and is documented in the WPC May 24, 2010 "Report of Groundwater Sampling" (WPC, 2010). During that sampling event, and preceding sampling events, numerous wells were excluded from sampling since they were inaccessible, missing, or destroyed.

As documented in a separate EIC report (EIC, 2011b) and in Section 1.0, EIC repaired or re-drilled five selected wells to better define the prevailing contaminant plume. The analytical data from the current sampling event therefore establishes a baseline of prevailing contamination conditions from which contaminant concentration trends may be tracked. Subsequent analysis is essential in establishing trends to verify whether natural attenuation of contaminants is in progress and determine if changes to the remedial strategy are required. The trend analysis is also useful in verifying if remedial objectives to meet Risk Reduction Type 4 Standards (RRS), established in the VIRP, are being met. Trends in contaminant degradation rates, and plume stability will be determined using data collected from subsequent quarterly analyses.

Since the five new wells had not been surveyed and since some well repairs led to changes in the top of casing (TOC) elevations, and also since certain site features were not shown or were incorrectly shown on current site maps, EIC contracted a Georgia-licensed land surveyor to conduct a survey of

these wells and site features. This survey is documented in a separate EIC report (EIC, 2011c), and in Section 1.0.

This program entails collecting groundwater samples from wells within the previously established area of concern with dissolved chlorinated volatile organic compounds (CVOCs) and volatile organic compounds (VOCs) contamination for analysis. During this event, EIC collected 19 groundwater samples from 19 wells.

Based on subsequent sampling events, EIC conducts trend analysis to verify whether natural attenuation of contaminants is in progress since the baseline sampling event and to determine if changes to the remedial strategy are required. This trend analysis is also useful in verifying if remedial objectives to meet Risk Reduction Type 4 Standards (RRS) are being met. Trends in contaminant degradation rates, and plume stability were determined using data collected from both sampling events.

# 1.0 PROJECT BACKGROUND

The site is currently listed on the State of Georgia Hazardous Site Response Act (HSRA) site inventory as Site Number 10464 Paktank Corporation – Savannah Terminal (now VOPAK). A tetrachloroethene, also known as perchloroethene (PCE), release occurred at the VOPAK Terminal (site) between December 1972 and April 1975 from Tank 24 in Tank Farm #2 impacting the soil and groundwater (ERM, 2005). Over the years the PCE has degraded into other dissolved CVOCs including trichloroethene (TCE), cis 1, 2 dichloroethene (1,2-DCE), and vinyl chloride (VC). These CVOCs resulted in a contaminated groundwater plume. To a limited extent, Benzene, Ethylbenzene, Toluene, and Xylenes (BTEX) hydrocarbons also occur within the CVOC plume. These eight contaminants constitute the primary constituents of concern (COC) that have been tracked under the previous monitoring and remedial program.

Prior to the approval of the VIRP, mitigation of the PCE release was enforced under consent order No. EPD-HSR-384 issued by the Georgia Environmental Protection Division (EPD). The consent order involved implementation of an approved corrective action plan (CAP) (ERM, 2005). The CAP projected a 20-year cleanup time period.

The remedial action under the CAP entailed enhanced bioremediation with natural attenuation. As such, sodium and ethyl lactate, soybean oil and pH buffer was periodically injected into 18 injection wells (ERM, 2010). After 8 injection events for bioremediation, however, VOPAK realized that the PCE levels had actually increased in a number of wells. The end result was the potential for perpetual remediation at substantial operation and maintenance costs.

Consequently, EIC recommended that VOPAK enroll in the EPD's Voluntary Remediation Program (VRP) to define a pathway for conducting remediation in a more effective and timely manner. EIC originally submitted the VIRP application to the EPD in October 2010. After a review by the EPD, EIC submitted a revised VIRP application in April 2011 (EIC, 2011a). The EPD

approved the VRP application with certain conditions on August 31, 2011. As such, the VRP standards now supersede the CAP requirements.

Under the approved VIRP, all available monitoring wells within the PCE/BTEX contaminant plume were proposed by EIC for the monitored natural attenuation (MNA) remedial approach. These included wells previously utilized for MNA (MW-17R, MW-18R, PAN-MW-9, and MW-22R) and "performance monitoring wells" that included shallow wells PAN-MW-10, MW-16, MW-19, MW-23, MW-24R, MW-25, MW-26R, MW-27, and deep well MW-15. EIC proposed that existing monitoring wells LAW-PZ-8R and MW-29, that had previously not been utilized, would be added for MNA/performance monitoring. EIC also proposed that shallow monitoring wells MW-20, MW-21, and MW-28, that had been reported as missing in a previous Well Inventory Checklist (WPC, 2010), would be replaced. The previous well inventory had also listed the deep well MW-14 as missing, however, considering that MW-15 was also a deep well, EIC deferred replacing MW-14 until an evaluation for deeper contamination is completed.

### 1.1 REPLACEMENT WELLS

Accordingly, during two site visits in April 2011, EIC installed three replacement wells for MW-20, MW-21, and MW-28 and also two additional replacement wells for MW-22R (which had become filled with sediment and could not be repaired) and MW-27 (which could not be located) that EIC determined were necessary during the first site visit (EIC, 2011b). As such, MW-20 was replaced with MW-32, MW-21 with MW-30, MW-22R with MW-33, MW-27 with MW-31, and MW-28 with MW-34, respectively. When MW-31 was installed, however, EIC discovered what is presumed to be MW-27 in good condition (EIC, 2011b). During well installation activities, EIC also inventoried the location and condition of injection wells (EIC, 2011b).

### 1.2 WELL SURVEY

On June 29 and 30, 2011 a Georgia-licensed land surveyor commissioned by EIC surveyed the location and TOC elevations (X, Y, Z data) of 19 monitoring wells (the same 19 wells EIC sampled) and certain site features selected by EIC (EIC, 2011c) in the NAVD 29 Datum convention. EIC selected this datum convention as it is consistent with previous wells surveys in this area. Site features surveyed included fence lines, road edges, fuel tanks, and a vehicle scale shed on adjacent property. EIC determined from the survey that various wells, site features, scale, and the north arrow had been incorrectly depicted in previous base maps. From the data and maps provided by the surveyor, EIC updated the site basemap to correctly illustrate the locations of wells and the site features mentioned above.

## 2.0 PROJECT OBJECTIVES

In proposal 19-103570, EIC proposed to collect groundwater samples from 19 monitoring wells illustrated in Figure 1. Since the previous injection program was terminated in 2009, the current

sampling program will establish a new baseline. Data from this sampling program combined with subsequent sampling events, will assist VOPAK in meeting the following goals set forth in the VIRP. These include:

- Establish a baseline horizontal and vertical extent of the prevailing contaminant plume.
- Review plume stability.
- Track MNA by monitoring the groundwater concentrations of VOCs/CVOCs within the existing plume.
- Determine if the prevailing groundwater contaminant concentrations meet or is trending towards meeting the established RRS.

The following sections outline the tasks performed by EIC to meet these objectives.

# 3.0 GROUNDWATER SAMPLING FIELD PROGRAM

During the period from October 25 through October 27, 2011, EIC collected 19 groundwater samples from 19 wells identified in Section 1.0 to submit for VOC/CVOC analysis. The following sections describe EIC's sampling technical approach.

## 3.1 SAMPLING PROTOCOL

The groundwater sampling program was conducted in accordance with the current U.S. EPA groundwater sampling procedure "Field Branches Quality System and Technical Procedures" (FBQSTP) per the EPD. Each monitoring well was gauged, purged, and sampled following the "low-flow" purge technique established in the standard operating procedure (SOP) SESDPROC-301-R1 under the FBQSTP.

## 3.2 SITE ACCESS

Prior to EIC's site visit, EIC coordinated with the Georgia Ports Authority (GPA) and VOPAK in gaining access to collect groundwater samples from off-site wells MW-17, MW-32, and MW-34 located on GPA property. Since access to MW-34 was only possible through GAF Materials Corporation (GAF) property, EIC obtained GAF's permission to enter their facility to sample this well.

## 3.3 WELL-HEAD VOC MONITORING

Prior to purging, EIC measured volatile organic compounds (VOCs) concentrations in air in parts per million (PPM) with a photo ionization detector (PID). EIC collected three measurements at each well. The first was a background measurement within 2 feet of the TOC with either the stickup lid or flush-to-grade (FTG) vault closed. After EIC had opened the stickup lid or FTG vault, but had not yet opened the well cap on the TOC, EIC took a second VOC reading of air

within the formerly enclosed space. Finally, after EIC had opened the well cap, EIC took a third VOC reading of air within the well head.

## 3.4 GROUNDWATER SAMPLING PROCEDURE

EIC gauged each well with a Solinst Model 122 interface meter (oil/water interface probe) to determine the depth to groundwater. Based on the depth to groundwater, EIC determined the depth to set the sampling tubing intake. The tubing intake was typically set greater than 2 feet below the groundwater surface but was lowered below this depth if the water level dropped to the depth of the intake during pumping. At MW-15, however, the intake was set approximately 6 feet below the water level to prevent the recovery of apparent vegetable oil. A Masterflex Model 7570-10 peristaltic pump was utilized for purging and sampling. Dedicated disposable ¼-inch internal diameter (ID) Teflon tubing was utilized in all wells for purging. Groundwater from each monitoring well was pumped via the peristaltic pump through a Horiba U-52-2 Water Quality Meter with a flow-through cell. During purging, water quality parameters, including temperature, specific conductivity, pH, dissolved oxygen (DO), turbidity, and oxidation-reduction potential (ORP); rate of evacuation; and depth to water (well diameter permitting) were measured at approximately 5-minute intervals until certain parameters stabilized per SESDPROC-301-R1. EIC considered that parameters were stabilized when 3 consecutive readings were within ± 0.1 for pH, ± 10% for Specific Conductivity, or ± 10% for Temperature and when Turbidity was at or below 10 Nephelometric Turbidity Units (NTUs) or had stabilized (after reasonable attempts). These measurements were recorded on EIC's Well Purging and Sampling Data field logs (Attachment A). EIC also recorded field activities in a field book. EIC deposited all purge water into a steel 55-gallon drum provided by VOPAK for later disposal by VOPAK. EIC placed a green Non-Hazardous label on this drum.

At each well, after water quality parameters stabilized, groundwater samples were then collected, per SESDPROC-301-R1, utilizing the "soda straw method" whereby the Teflon tube was pulled from the well, the peristaltic pump run in reverse, and sample bottles filled from the tube. To ensure that no groundwater from the peristaltic pump head reached the sample bottles during sample collection, EIC utilized a minimum of 20 feet of tubing. All 19 samples were submitted to Test America (lab), a Georgia-certified laboratory located in Savannah, for analysis of volatile organic compounds via EPA method 8260B.

EIC initiated field sampling activities on the afternoon of October 25 at well MW-34 on a Georgia Ports Authority (GPA) property easement adjacent to GAF property. EIC then proceeded to collect groundwater samples from MW-32 and then the nearby MW-17R on GPA property. On October 26, EIC collected a new 55-gallon steel drum and a wooden pallet from the drum storage area to store purge water and placed this drum along the west shoulder of Hart Street between Tank Farm #2 and Tank Farm #3. EIC then continued to collect groundwater samples from the following wells in the following order: MW-16, MW-30, MW-26R, MW-15, MW-18R, MW-24R, MW-29, MW-33, PAN-MW-9, PAN-MW-10, and LAW-PZ-8R.

Based on observations during gauging, EIC determined that in well MW-15, an apparent degraded vegetable oil layer was floating on the surface. This fluid was apparently mistakenly poured into this well during previous injection activities. To prevent the recovery of this fluid from contaminating

the groundwater sample, EIC employed a custom-built apparatus consisting of a decontaminated 6-inch segment of ½-inch ID plastic tubing sealed with electrical tape on one end and with a hole on the opposite end to attach a string. EIC attached a string to this device, filled it with DI water, placed the end of the ¼-inch Teflon tubing in this device and lowered it and the tubing through the oil until it was 6.10 feet below the water surface. EIC then lowered the device approximately 3 feet below the tubing intake. EIC then operated the peristaltic pump and collected a groundwater sample. After the tubing was retrieved, the device and string was removed from the well and disposed of.

On October 27, EIC completed collecting groundwater samples from the remaining wells in the following order: MW-25, MW-19, MW-23, MW-31, and MW-27. Table 1 summarizes groundwater quality field parameters after stabilization and prior to sample collection. It should be noted that at 10 of the wells, turbidity levels of 10 NTUs or lower could not be reached after reasonable attempts were made to achieve this after pH, conductivity, and temperature parameters had stabilized. Table 2 summarizes the well purging data for each well. As discussed in Section 3.1, EIC gauged each well prior to purging. This initial gauging data is tabulated in Table 3. EIC coordinated the pickup of the first 14 samples and a trip blank by the lab the morning of October 27. EIC hand-delivered the remaining 5 samples and a trip blank to the laboratory the afternoon of October 27. The laboratory report is included as Attachment B.

## 4.0 QUALITY ASSURANCE AND QUALITY CONTROL

Two trip blank samples supplied by the lab, that remained in each sample set, were also submitted to the lab for validation of analytical results. The blank samples were submitted for the same EPA 8260B analysis as the 19 groundwater samples. All sample bottles were properly sealed and labeled in the field. Each sample set was then stored with ice and a temperature blank in insulated containers ("coolers") provided by the laboratory. Completed chain of custody forms accompanied all samples.

To prevent cross-contamination, dedicated disposable Teflon tubing was used to collect all samples. EIC's oil/water interface probe was field decontaminated prior to use and between sample locations by washing in an Alconox detergent solution and rinsing with lab-supplied de-ionized water. After each sample was collected, the Horiba water quality parameters instrument with flow-through cell was decontaminated by pumping 1,500 to 2,000 mL of laboratory-supplied de-ionized (DI) water through it with the peristaltic pump. As needed, the instrument was also cleaned by periodically disassembling and cleaning the flow-through cell by spraying it and the parameter sensors with pressurized DI water and wiping with Q-tips and paper wipes.

## 5.0 DATA EVALUATION

EIC conducted an evaluation of the data compiled from field data and laboratory analysis to determine the current groundwater potentiometric surface and the horizontal extent of the prevailing contaminant plume. Since this sampling event included data from new wells and repaired

wells installed since the last two previous sampling events (for CVOCs only in April 2010 and for VOCs/CVOCs on Sept 2009) the analytical data serves as a baseline for further evaluation.

## 5.1 GROUNDWATER POTENTIOMETRIC MAP

From gauging data summarized in Table 3, EIC prepared a groundwater potentiometric surface map (Figure 2). From this figure it clear that the primary feature in the potentiometric surface is a trough that (beginning in the vicinity of the office) slopes downward towards the east then (beginning in the vicinity of Tank 24 in Tank Farm #2) turns toward the north, extending past Tank 35 also in Tank Farm #2. As such, groundwater would be expected to flow along this topographical trough towards the north. In the previous potentiometric map prepared from the September 2009 gauging data (EIC, 2011a), the potentiometric surface does not have this trough feature but, rather, has a uniform east to northeast downward slope.

## 5.2 HORIZONTAL EXTENT OF CONTAMINANT PLUMES

The analytical data from the groundwater sampling program and the historic analytical data are tabulated in Table 4. Figure 3 illustrates the COC results for each sampled well. All parameters that exceeded the revised Type 4 risk reduction standards are marked in red.

### 5.2.1 CVOC Plume

Figures 4 through 7 illustrate the horizontal extent of the current CVOC contaminant plume comprised of PCE, TCE, 1,2-dicholorbenzene, and vinyl chloride, respectively. In preparing these plume maps, EIC utilized the same contour intervals as those illustrated in the CAP and in previous ERM annual reports, and in the revised VRP submittal. This allows for a comparative evaluation of the plume maps over time. Also, the limits of the RRS concentrations and the delineation criterion are illustrated to evaluate the extent of dissolved CVOCs that require remediation.

<u>PCE Plume</u>

Referring to Figure 4, the highest concentrations of PCE occurred in MW-33, followed sequentially by PAN-MW-9, MW-29, and then by LAW-PZ-8R. As such, the horizontal distribution of the peak CVOC plume trends south to north from the area of LAW-PZ-8R to MW-33 and then to PAN-MW-9 and MW-29. This appears to indicate that the plume is aligned along the same direction as groundwater flow indicated on the groundwater potentiometric map (Figure 2). As such, the shape and position of the peak plume is relatively consistent with that depicted in the September 2009 PCE contour map. However, the PCE concentration of 5,200 µg/L at MW-33 (a new well drilled in the vicinity of MW-22R,) is higher than the 3,000 µg/L reported for MW-22R in September 2009. The concentration may be higher due to MW-33 being located closer to the peak plume than the former MW-22.

From Figure 4, the peak thickness of the PCE plume is entirely within Tank Farm #2. PCE concentrations are above RRS but at significantly lower concentrations than those within the peak plume in three wells - MW-15 (deep), MW-24R, and MW-32. This indicates that the RRS of the PCE plume extends down-gradient approximately 440 feet towards the north-northeast yet also 140 feet up-gradient towards the south-southwest from the original release location at Tank 24. Since the CVOC concentrations in MW-16, MW-17R, MW-30, and MW-34 (east of the CVOC plume) and wells MW-18R, MW-19, MW-23, MW-25, MW-27, and MW-31, (west of the CVOC plume) are below RRS, the PCE plume does not appear to be migrating east or west beyond the vicinity of Tank Farm #2.

CVOC Degradation Products

Other CVOCs resulting as degradation products of PCE, have been historically identified at the site. In reviewing Figures 4 through 7, EIC made the following observations:

1. It is apparent that the TCE plume has a similar footprint as PCE.
2. Although the 1,2 – DCE plume lies in the same location as PCE, the footprint is somewhat larger and extents farther towards the north than the PCE plume. A much smaller isolated plume of 1,2 – DCE is located in the area of MW-16. As the groundwater flow direction in the area of MW-16 is primarily towards the north and this smaller plume is side-gradient of the larger plume, EIC is uncertain as to the source of this smaller plume.
3. Low concentrations of vinyl chloride (VC) are present within the PCE footprint and the VC plume extends well beyond the PCE footprint, forming the largest of the four CVOC plumes mapped. The VC plume extends the farthest to the northwest of the four CVOCs, extending beyond MW-27. A much smaller isolated plume of VC is located in the area of MW-16.

All these observations are indicative of potential biotransformation in progress. Considering that the current sampling event serves as a baseline, data from future sampling event will be utilized to evaluate the overall bioremediation potential at the site.

### 5.2.2 VOC Plume

Figures 8 through 11 illustrate the horizontal extent of the current VOC contaminant plume comprised of benzene, toluene, ethylbenzene, and total xylenes, respectively. In preparing these plume maps, EIC utilized the same contour intervals as those illustrated in the CVOC maps. This allows for a relative comparison of the plume maps between VOC and CVOC limits. Also, the limits of the RRS concentrations and the delineation criterion are illustrated to evaluate the extent of dissolved VOCs that require remediation.

Referring to Table 4, in general, the highest concentrations of VOCs occurred in LAW-PZ-8R, followed by PAN-MW-9, and then MW-29. Also, benzene concentrations were above RRS at MW-15 (deep) and MW-24R. In reviewing Figures 8 through 11, EIC made the following observations:

1. The peak concentration of the benzene plume lies in the vicinity of LAW-PZ-8R and extends towards the northeast. The plume footprint above Type 4 RRS and delineation

criteria for benzene generally lies just within or immediately south of Tank Farm #2 and within the footprint of the PCE plume.

2. The peak of the toluene plume lies in the vicinity of LAW-PZ-8R. The plume does not exceed the Type 4 RRS, however, the plume footprint above delineation criteria for toluene is restricted to the near vicinity of LAW-PZ-8R.
3. The ethylbenzene plume has two peaks with the primary one located at well LAW-PZ-8R and a secondary one in the vicinity of wells PAN-MW-9 and MW-29. As there are two plume peaks, there are two separate footprints above Type 4 RRS and delineation criteria (both 700 µg/L) for ethylbenzene with each of these footprints lying in the vicinity of Tank Farm #2 with the southern footprint immediately south of Tank Form 2.
4. The peak of the total xylenes plume lies in the vicinity of LAW-PZ-8R and extends towards the northeast. The plume footprint above Type 4 RRS and delineation criteria for total xylenes (both 10,000 µg/L) generally is restricted to the near vicinity of LAW-PZ-8R to the south, east, and west and extending approximately 80 feet to the northeast of LAW-PZ-8R.

With the exception of the ethylbenzene plume, all four VOC COC plumes, have a single peak at LAW-PZ-8R that extends towards the northeast. All four plumes are within the vicinity of Tank Farm #2.

## 5.3 VERTICAL EXTENT OF CONTAMINANT PLUMES

There are two deep wells, namely MW-14 and MW-15, reported in historical documents. Since MW-14 could not be located, MW-15 is the only deep well that was available for sampling. According to historical well construction tables, this well has a screened interval of from 46.7 to 56.7 feet below ground surface (BGS). EIC, however, was unable to obtain a well construction diagram of this well to confirm its validity in utilizing this well to monitor vertical migration of COCs.

From Figure 3, in MW-15, concentrations were above RRS for each of the four CVOCs and concentrations of the VOC benzene was above RRS. Referring to Table 4, all eight COC concentrations were greater than any of those historically reported for this well. As COCs could possibly have migrated vertically through the annulus space of MW-15, causing increased concentrations of these constituents, EIC will continue its attempt to locate the well construction details for MW-15.

During the sampling event, EIC encountered LNAPL floating in MW-15 that appeared to be partially degraded vegetable oil. EIC suspects that the material may be soybean oil that was mistakenly injected into this well during the injection program. Further investigation, however, is necessary to determine the source and composition of this LNAPL.

## 5.4 PLUME STABILITY

### 5.4.1 CVOC Plume

As discussed in Section 5.2.1, a substantial portion of the CVOC plume has remained stationary within Tank Farm #2. However, as concentrations of CVOCs above RRS in the larger plume occur in well MW-32 which, as indicated by Figure 2, is down-gradient of the plume, some degree of migration appears to be occurring towards the north. This contamination, however, apparently didn't reach MW-17R, that lies further north. The isolated small 1,2-DCE and VC plumes in the area of MW-16 may be remnants from the larger plume that has receded from this area. From Table 4-1 (EIC, 2011a), the former MW-20 (which lies in the vicinity of MW-32) had not been sampled since August, 2003, when all COCs from this well were below MDL, however levels of three CVOC COCs (PCE, 1,2-DCE, VC) were above RRS in MW-32 from the current sampling event.

As discussed in Section 5.3, the CVOC vertical extent is inconclusive and will be evaluated further. From EIC's evaluation of both the horizontal and vertical extents of the CVOCs, EIC is uncertain whether the plume will migrate farther northward.

### 5.4.2 VOC Plume

As discussed in Section 5.2.2, the VOC plume in general appears to be primarily situated within or immediately south of Tank Farm #2 and is stable and not apparently actively migrating horizontally with the ethylbenzene and total xylenes. Ethylbenzene and total xylenes COCs at MW-29 at the interior of the plume have increased significantly since the previous VOC sampling event of September 2009. Referring to Table 4, for MW-15 (deep), all four BTEX COCs had the highest historical concentrations yet recorded during the current sampling event. EIC is uncertain as to why the BTEX concentrations have increased to this extent. Further evaluation of the vertical extent of COCs is necessary. As the VOC plume lies entirely within or immediately south of Tank Farm #2, it does not appear to impact the Savannah River. Also, since the VOC plume lies north of MW-18R and MW-34, it appears to neither impact neither the GPA nor GAF properties to the south.

# 6.0 CONCLUSIONS

From the baseline horizontal and vertical plume analysis, the CVOC plume appears to be relatively stable. However, there appears to be horizontal migration of the plume towards the north and onto GPA property near the Savannah River to a limited extent.. Further analysis of the vertical extents of COVs is required to determine if vertical migration has occurred or occurred due to MW-15 well construction. A portion of the CVOC plume extends into GPA property to the north and GAF property to the south.

NOTES:

All parameter measurements were taken after parameters had stabilized and prior to sample collection

Field parameters were recorded from 10/25/2011 TO 10/27/2011

Parameters (other than volume) were measured with a Horiba U-52-2 Instrument with Flow-Through Cell

Volume was measured with a 2,000 mL graduated cylinder

# Table 2: Well Purging Data

| Well ID | Date of Purge | Purge Time (min) | Purge Volume (mL) | Average Purge Rate (mL/min) | Hose Intake Location in Well below TOC (ft) |

# Table 3: October 2011 Well Gauging Data, VOPAK Terminal Savannah, Savannah, Georgia

| Well ID # | TOC Elevation* | DTP | DTW | Groundwater Surface Elevation | Notes |
|---|---|---|---|---|---|
| (Well Diameter, in.) | ft. | ft. | ft. | ft. | |
| LAW-PZ-8R (1) | 14.02 | ND | 6.27 | 7.75 | |
| PAN-MW-9 (2) | 12.59 | ND | 6.35 | 6.24 | Well was repaired by EIC on April 6, 2011 |
| PAN-MW-10 (2) | 13.81 | ND | 10.36 | 3.45 | |
| MW-15 (1) | 10.07 | ND | 2.92 | 7.15 | Apparent vegatable oil found floating on water table. This is possibly that of the sodium, ethyl lactate, soybean oil, pH buffer solution previously periodically injected into injection wells but apparently mistakenly injected into this monitoring well. |
| MW-16 (1) | 17.01 | ND | 11.34 | 5.67 | Well was repaired by EIC on April 6, 2011 |
| MW-17R (2) | 15.89 | ND | 11.96 | 3.93 | |
| MW-18R (1) | 14.12 | ND | 6.47 | 7.65 | Well was repaired by EIC on April 6, 2011 |
| MW-19 (1) | 14.91 | ND | 6.80 | 8.11 | Well was repaired by EIC on April 6, 2011 |
| MW-23 (1) | 10.39 | ND | 4.00 | 6.39 | |
| MW-24R (2) | 11.81 | ND | 5.95 | 5.86 | |
| MW-25 (1) | 14.76 | ND | 6.85 | 7.91 | Well was repaired by EIC on April 6, 2011 |
| MW-26R (1) | 10.61 | ND | 3.22 | 7.39 | |
| MW-27 (1) | 9.93 | ND | 4.87 | 5.06 | |
| MW-29 (0.75) | 11.73 | ND | 6.02 | 5.71 | |
| MW-30 (2) | 11.23 | ND | 4.95 | 6.28 | Well installed by EIC on April 6, 2011 |
| MW-31 (2) | 9.67 | ND | 5.26 | 4.41 | Well installed by EIC on April 28, 2011 |
| MW-32 (2) | 11.70 | ND | 6.47 | 5.23 | Well installed by EIC on April 25, 2011 |
| MW-33 (2) | 11.61 | ND | 5.07 | 6.54 | Well installed by EIC on April 28, 2011 |
| MW-34 (2) | 10.81 | ND | 3.41 | 7.40 | Well installed by EIC on April 26, 2011 |

NOTES:

TOC = Top of Casing

DTP = Depth to Product below TOC

DTW = Depth to Water below TOC

ND = Not Detected

* TOC elevations are from well survey conducted by EMC Engineering on June 30, 2011 and is of the NAVD 29 Datum convention

Value exceeds a risk reduction standard
NR = not reported by the lab
NS = not sampled
NI = not installed
NU = not used
NL = not located
< = less than indicated value
< 5/< 500 = sample was analyzed twice
J this is an estimated value that is above the method detection limit but below the practical quantitation limit.
The sample denoted MW-10 on 12/18/98 is believed to have been collected from MW-9, I.e. the two samples were mislabeled. This table shows what is believed to be correct.
Risk reduction standard, the higher of the Type 3 or 4 from Table 2 of Risk Reduction Standards dated August 13, 2001
LAW-PZ-8 was found damaged during June 2006 sampling event and was not sampled.
Type 3 or 4 RRS from 2/1/1991 to 4/26/2010 from CAP
RRS beginning on 4/27/2011 from VRP Application
*1 MW-20 was not located (possibly paved over), MW-32 was installed as a replacement
*2 MW-21 was not located, MW-30 was installed as a replacement
*3 MW-22 was filled with silt above water level and could not be used, MW-33 was installed as a replacement
*4 MW-28 was not located, MW-34 was installed as a replacement

NS = Not sampled
NI = Well Not yet Installed
LAW-PZ-8 was found damaged during June 2006 sampling event and was not sampled. It was replaced by LAW-PZ-8R on 10/9/2006.
MW-17 was replaced by MW-17R on 10/10/2006.
MW-26 was replaced by MW-26R on 10/9/2006.
*1 MW-20 was not located (possibly paved over), MW-32 was installed as a replacement
*2 MW-21 was not located, MW-30 was installed as a replacement
*3 MW-22 was filled with silt and could not be sampled, MW-33 was installed as a replacement
*4 MW-28 was not located, MW-34 was installed as a replacement
*5 MW-27 was not possitively identified but is assumed. MW-31 was installed as a replacement for MW-27 but lies approximately where MW-27 had been shown on previous site maps

**Narrative**

**Job Narrative**
**680-73799-1**

**Receipt**
All samples were received in good condition within temperature requirements.

**GC/MS VOA**
Method(s) 8260B: A full list spike was utilized for this method. Due to the large number of spiked analytes, there is a high probability that one or more analytes will recover outside acceptance limits. The laboratory's SOP allows for four analytes to recover outside criteria for this method when a full list spike is utilized. The LCS associated with batch 220123 had one analyte outside control limits; therefore, re-extraction/re-analysis was not performed. These results have been reported and qualified.

Method(s) 8260B: A full list spike was utilized for this method. Due to the large number of spiked analytes, there is a high probability that one or more analytes will recover outside acceptance limits. The laboratory's SOP allows for 4 analytes to recover outside criteria for this method when a full list spike is utilized. The LCS/LCSD associated with batch 220251 each had 1 analyte outside control limits; therefore, re-extraction/re-analysis was not performed. These results have been reported and qualified.

Method(s) 8260B: A full list spike was utilized for this method. Due to the large number of spiked analytes, there is a high probability that one or more analytes will recover outside acceptance limits. The laboratory's SOP allows for 4 analytes to recover outside criteria for this method when a full list spike is utilized. The LCS/LCSD associated with batch 220479 each had 1 analyte outside control limits; therefore, re-extraction/re-analysis was not performed. These results have been reported and qualified.

Method(s) 8260B: The method blank for batch 220479 contained 1,2,4-trichlorobenzene above the method detection limit. This target analyte concentration was less than the reporting limit (RL); therefore, re-extraction and/or re-analysis of samples was not performed.

Method(s) 8260B: The continuing calibration verification (CCV) for analytical batch 220447 exceeded control limits for bromomethane. This compound has been identified as a poor performing analyte when analyzed using this method; therefore, re-extraction/re-analysis was not performed. Additionally, the samples associated with this CCV were previously analyzed at a lower dilution in a clock in which this analyte was within control criteria in the CCV, and it was not detected. Both sets of data have been reported.

Method(s) 8260B: A full list spike was utilized for this method. Due to the large number of spiked analytes, there is a high probability that one or more analytes will recover outside acceptance limits. The laboratory's SOP allows for 4 analytes to recover outside criteria for this method when a full list spike is utilized. The LCS associated with batch 220477 had 1 analyte outside control limits; therefore, re-extraction/re-analysis was not performed. These results have been reported and qualified.

No other analytical or quality issues were noted.

# Method Summary

Client: Environmental International Corporation
Project/Site: GW Sampling PN #390010 / Savannah GA

TestAmerica Job ID: 680-73799-1

| Method | Method Description | Protocol | Laboratory |
|---|---|---|---|
| 8260B | Volatile Organic Compounds (GC/MS) | SW846 | TAL SAV |

**Protocol References:**

SW846 = "Test Methods For Evaluating Solid Waste, Physical/Chemical Methods", Third Edition, November 1986 And Its Updates.

**Laboratory References:**

TAL SAV = TestAmerica Savannah, 5102 LaRoche Avenue, Savannah, GA 31404, TEL (912)354-7858

## Qualifiers

### GC/MS VOA

| Qualifier | Qualifier Description |
|---|---|
| J | Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value. |
| E | Result exceeded calibration range. |
| D | Surrogate or matrix spike recoveries were not obtained because the extract was diluted for analysis; also compounds analyzed at a dilution may be flagged with a D. |
| * | LCS or LCSD exceeds the control limits |
| B | Compound was found in the blank and sample. |

## Glossary

| Abbreviation | These commonly used abbreviations may or may not be present in this report. |
|---|---|
| ☼ | Listed under the "D" column to designate that the result is reported on a dry weight basis |
| %R | Percent Recovery |
| CNF | Contains no Free Liquid |
| DL, RA, RE, IN | Indicates a Dilution, Reanalysis, Re-extraction, or additional Initial metals/anion analysis of the sample |
| EDL | Estimated Detection Limit |
| EPA | United States Environmental Protection Agency |
| MDL | Method Detection Limit |
| ML | Minimum Level (Dioxin) |
| ND | Not detected at the reporting limit (or MDL or EDL if shown) |
| PQL | Practical Quantitation Limit |
| RL | Reporting Limit |
| RPD | Relative Percent Difference, a measure of the relative difference between two points |
| TEF | Toxicity Equivalent Factor (Dioxin) |
| TEQ | Toxicity Equivalent Quotient (Dioxin) |

# Login Sample Receipt Checklist

Client: Environmental International Corporation

Job Number: 680-73799-1

**Login Number: 73799**

**List Source: TestAmerica Savannah**

**List Number: 1**

**Creator: Conner, Keaton**

| Question | Answer | Comment |
|---|---|---|
| Radioactivity either was not measured or, if measured, is at or below background | N/A | |
| The cooler's custody seal, if present, is intact. | True | |
| The cooler or samples do not appear to have been compromised or tampered with. | True | |
| Samples were received on ice. | True | |
| Cooler Temperature is acceptable. | True | |
| Cooler Temperature is recorded. | True | |
| COC is present. | True | |
| COC is filled out in ink and legible. | True | |
| COC is filled out with all pertinent information. | True | |
| Is the Field Sampler's name present on COC? | True | |
| There are no discrepancies between the sample IDs on the containers and the COC. | False | -9 vials say MW-26 coc has MW-26R |
| Samples are received within Holding Time. | True | |
| Sample containers have legible labels. | True | |
| Containers are not broken or leaking. | True | |
| Sample collection date/times are provided. | True | |
| Appropriate sample containers are used. | True | |
| Sample bottles are completely filled. | True | |
| Sample Preservation Verified. | True | |
| There is sufficient vol. for all requested analyses, incl. any requested MS/MSDs | True | |
| VOA sample vials do not have headspace or bubble is <6mm (1/4") in diameter. | True | |
| Multiphasic samples are not present. | N/A | |
| Samples do not require splitting or compositing. | N/A | |
| Residual Chlorine Checked. | N/A | |

## Job ID: 680-73812-1

**Laboratory: TestAmerica Savannah**

**Narrative**

**Job Narrative**
**680-73812-1**

**Receipt**
All samples were received in good condition within temperature requirements.

**GC/MS VOA**
Method(s) 8260B: The method blank for batch 220351 contained 1,2,4-trichlorobenzene above the method detection limit. This target analyte concentration was less than the reporting limit (RL); therefore, re-extraction and/or re-analysis of samples was not performed.

Method(s) 8260B: A full list spike was utilized for this method. Due to the large number of spiked analytes, there is a high probability that one or more analytes will recover outside acceptance limits. The laboratory's SOP allows for 4 analytes to recover outside criteria for this method when a full list spike is utilized. The LCS/LCSD associated with batch 220479 each had 1 analyte outside control limits; therefore, re-extraction/re-analysis was not performed. These results have been reported and qualified.

Method(s) 8260B: The method blank for batch 220479 contained 1,2,4-trichlorobenzene above the method detection limit. This target analyte concentration was less than the reporting limit (RL); therefore, re-extraction and/or re-analysis of samples was not performed.

No other analytical or quality issues were noted.

**Comments**
No additional comments.

TestAmerica Job ID: 680-73812-1

## Qualifiers

### GC/MS VOA

| Qualifier | Qualifier Description |
|---|---|
| J | Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value. |
| B | Compound was found in the blank and sample. |
| * | LCS or LCSD exceeds the control limits |

## Glossary

| Abbreviation | These commonly used abbreviations may or may not be present in this report. |
|---|---|
| ☼ | Listed under the "D" column to designate that the result is reported on a dry weight basis |
| %R | Percent Recovery |
| CNF | Contains no Free Liquid |
| DL, RA, RE, IN | Indicates a Dilution, Reanalysis, Re-extraction, or additional Initial metals/anion analysis of the sample |
| EDL | Estimated Detection Limit |
| EPA | United States Environmental Protection Agency |
| MDL | Method Detection Limit |
| ML | Minimum Level (Dioxin) |
| ND | Not detected at the reporting limit (or MDL or EDL if shown) |
| PQL | Practical Quantitation Limit |
| RL | Reporting Limit |
| RPD | Relative Percent Difference, a measure of the relative difference between two points |
| TEF | Toxicity Equivalent Factor (Dioxin) |
| TEQ | Toxicity Equivalent Quotient (Dioxin) |

**Tax Parcel: 1-0618-01-003L**

Dear Mr. Metzger:

On behalf of VOPAK Terminal Savannah, Inc. Environmental International Corporation (EIC) is pleased to submit the attached fifth VIRP Semi-annual Progress Report for the above referenced site.

Enclosed are the following:

1. One signed and sealed certification page for the Semiannual Report.
2. One bound paper copy of the Fifth VIRP Semi-annual Progress Report.
3. Two Compact Discs each with the report in searchable PDF format.

If you have any questions regarding this submittal, please contact Mr. Branden Jones of VOPAK at 912-964-1811 extn.114 or me at the above location.

Sincerely,
ENVIRONMENTAL INTERNATIONAL CORPORATION

Raj Mahadevaiah, P.E., C.G.W.P.

B. Fifth VIRP Semiannual Report (CD)

SECTION 1

# 1. INTRODUCTION

On behalf of VOPAK, Environmental International Corporation (EIC) is pleased to submit the Fifth VIRP Semi-annual Progress Report for review by the Georgia Environmental Protection Division (EPD). This report was prepared as specified in the April 2, 2011 "Revised Voluntary Investigation and Remediation Plan (VIRP) and Application" that was approved by the EPD on August 31, 2011 under the Voluntary Remediation Program (VRP).

## 1.1 PRIMARY OBJECTIVES

The primary objective of this report is to present a compilation of tasks completed by EIC during the six-month time frame that covers the period from September 2013 through February 2014. This report documents the following tasks:

- EPD Comment letter
- Upgrades to monitoring well network
- Continued evaluation of COC trends
- Evaluation of down-hole MNA indicator parameters

The following sections describe each task.

SECTION

2

# 2. EPD COMMENT LETTER

VOPAK received a letter from the EPD, dated November 20, 2012, commenting on its review of the first two semi-annual progress reports that VOPAK submitted in February 2012 and August 2012. This letter is the last official response that VOPAK has received from the EPD. EIC provided a response to this letter in the fourth semiannual report (EIC, 2013b). The following subsections further address EPD's comments.

## 2.1 HORIZONTAL DELINEATION

The EPD's first comment was that vinyl chloride (VC) continued to exceed Type 1 RRS in well MW-27 requiring VOPAK to complete horizontal delineation beyond VOPAK'S property to the north. The facility immediately to the north of VOPAK's property is owned and operated by the Georgia Ports Authority (GPA). In addition, VOPAK recognized that the horizontal extent of the CVOC plume was not fully delineated to the south of VOPAK's property. The property to the south of VOPAK is owned by GAF Manufacturing, Inc. (GAF).

As described in Section 3, EIC proposed locations for three new groundwater monitoring wells to complete the off-site delineation of the CVOC plume. Immediately after VOPAK negotiated a right of entry with GPA, EIC installed the two new wells on GPA property in December 2013. MW-35 was installed at a location northwest and hydraulically down-gradient of MW-27 and well MW-36 was installed north of and down-gradient of MW-32. The third well, MW-37, was installed on GAF property south of and up-gradient of MW-26R. As described in Section 4, analytical results of COC concentrations from these new wells have enabled complete horizontal delineation of all COC down-gradient of the previously established COC footprint and enabled VOPAK in addressing EPD's concern about the VC plume down-gradient of MW-27. However, as also discussed in Section 4, analytical results from the new well MW-37 indicate the presence of CVOC hydraulically up-gradient of the original foot-print on GAF property. This potential extent will be further verified from the next quarterly sampling event.

## 2.2 WELL ABANDONMENT AND REHABILITATION

The EPD's second comment in the November 20, 2012 letter was that wells MW-14, MW-20, MW-21, and MW-28, that have not been located since April 2010, need to be located and added to the monitoring network. In the event that the wells in question were not useful for the monitoring program, EPD also required that VOPAK make every attempt to locate and properly abandon these wells. Also, EPD stated that the silted wells MW-15 and MW-22R should either be rehabilitated or properly abandoned.

As reported in the fourth VIRP semiannual report submitted in January 2013, EIC utilized a licensed surveyor to successfully locate well MW-14 but was unable to locate wells MW-20, MW-21, nor MW-28. In October, 2013 EIC re-developed MW-14, and added that well to the monitoring well network. In December 2013, as described in Section 3, EIC attempted to locate additional un-located wells IW-1, IW-2, IW-5, IW-13, and MW-26 for abandonment. Of these, EIC located wells IW-1, and IW-2. Also in December, EIC properly abandoned the known silted wells MW-15 and MW-22 and attempted to abandon wells IW-1, and IW-2.

At VOPAK's request, EIC utilized a licensed well driller to install a protective flush-to-grade vault at well MW-27 and to convert well LAW-PZ-8R from a stick-up to flush-to-grade construction. All well abandonments and modifications are illustrated in Figure 2-1.

SECTION

3

# 3. WELL UPGRADES

In continuing to meet the objectives set forth in the EPD's November 20, 2012 VIRP comments letter, VOPAK conducted various field tasks. These include attempts to locate the remaining un-located monitoring wells utilized for monitoring the COC within and surrounding Tank farm # 2, the abandonment of appropriate located wells and known damaged/silted wells, installation of three new monitoring wells to achieve horizontal delineation of COC, and modification of two existing wells. These tasks are summarized in Figure 2-1. The following subsections describe site activities completed by EIC.

## 3.1 EPD's COMMENTS

In the EPD's November 20, 2012 comments letter, the EPD's first comment was that *"vinyl chloride continues to exceed Type I RRS in MW-27. Please note that the August 13, 2013 semi-annual progress report must demonstrate complete horizontal delineation on all impacted properties"*. The EPD's second comment stated that of the wells *"MW-14, MW-20, MW-21, and MW-28* [that] *have not been located since April 2010"*, *"please attempt to locate these wells and add them to the well gauging network. If these wells are no longer needed, then every attempt should be made to locate and properly abandon these wells. Also the silted wells MW-22R and MW-15 should be rehabilitated or properly abandoned"* (EPD, 2012). This EPD Comments letter referred to a November 12, 2009 letter it issued to VOPAK and that listed wells IW-1, IW-2, IW-5, LAW-PZ-8, MW-17, and MW-26 as being paved over or destroyed during construction activities at the site.

As documented in the first and second VIRP semi-annual progress reports, VOPAK has attempted to locate the above un-located wells utilizing historical maps, a magnetometer, and by excavation. Prior to January 2013, LAW-PZ-8 and MW-17 were located and abandoned as they were deemed to be unsuitable for groundwater monitoring due to silting or other reasons (EIC, 2012b). Additionally, as documented in the Second Semiannual Progress Report, EIC determined that injection well IW-4 was silted and therefore abandoned that well (EIC, 2012e).

## 3.2 LOCATING WELLS

In January 2013, EIC retained EMC Engineering Services, Inc. (EMC) a professional licensed land surveyor to utilize historically established permanent benchmarks, historical surveys conducted by the surveyor, and a magnetometer to mark the locations of certain missing wells onsite. Additionally, EIC utilized the surveyor's historical data to determine the well names and coordinates of two unidentified/unnamed wells that were not properly depicted on available AutoCAD site maps. During the survey, EIC walked the site in an attempt to visually surface evidence of these wells. In an attempt to locate wells covered over by pavement or other site improvements, the surveyors utilized a magnetometer since the well vaults are typically made of cast iron.

During the survey, EIC successfully located well MW-14 that was a deep well with flush-to-grade (FTG) completion. The well had been hidden under a geo-synthetic liner within Tank Farm #2. Upon further evaluation, EIC determined that the well was in good condition and gauged the depth of this well. EIC determined that the depth-to-bottom of the well was 49.57 feet below top-of-casing that was close to the historical well construction data which listed the well as having a total depth of 49.44 feet below grade. Wells IW-7 and IW-8, which had previously been un-located, were identified as existing wells which had been incorrectly plotted on the historical basemap. Also, well IW-21 that was previously unidentified on historical site maps was also located. Based on previous survey coordinates and magnetometer readings, the surveyor also marked the locations of wells IW-1, IW-2, IW-5, and MW-26. However, wells IW-13, MW-20, MW-21, and MW-28 could not be located by the surveyor. EIC utilized the survey data (see Section 3.3.7) to update the site basemap utilized in all site figures.

## 3.3 WELL LOCATION, ABANDONMENT, AND RELATED TASKS

During two mobilizations in December 2013, EIC completed several tasks pertaining to the monitoring well network. The following sections describe the field tasks.

### 3.3.1 Utility Clearance

Prior to EIC's first mobilization to abandon wells and to install new wells, EIC contacted the Utilities Protection Center (UPC) via the "One Call Center" phone number. UPC contacted several public utility companies to mark the locations of any buried public utilities in the areas where installation of the three new wells were proposed. Utilities included power lines, gas lines, communication lines, and water lines. EIC coordinated with GPA and GAF on the completion of this task and provided them with a map of the proposed new well locations. GPA cleared the utilities on their property at the areas of the proposed wells MW-35 and MW-36 utilizing facility as-built drawings, as no public buried utilities were known to exist in the vicinity of these proposed wells. GAF facilitated the UPC locator on their property to clear the utilities in the area of the proposed well MW-37 and independently searched their records for buried utilities.

According to the UPC, the utilities at GAF were cleared prior to EIC's site visit to install MW-37. Regarding the wells on VOPAK property to be abandoned, EIC providing a map to VOPAK illustrating the proposed well abandonment locations for clearing facility utilities and product lines.

Prior to EIC's second mobilization, EIC again contacted the UPC to clear the utilities in the area of wells IW-1 and IW-2 to be abandoned, as VOPAK had informed EIC that there were possible natural gas and water utilities in the vicinity of the proposed well locations. During this mobilization, two utility locators visited the field and determined that no public buried utilities were in the area of either of these wells. These utilities, however, had no information on any private utilities on VOPAK property. VOPAK informed EIC that it would review its records on the locations of any buried utilities and product pipelines in the area of these wells.

### 3.3.2 Site Access

During both of EIC's mobilizations, EIC did not encounter any limitations in accessing the areas for the proposed well-related tasks. EIC coordinated with VOPAK, GPA, and GAF regarding all site activities for access, as needed.

### 3.3.3 Well Locating Via Excavations

Utilizing the paint marks placed on the pavement by the surveyor that identified potential locations of wells IW-1, IW-2, IW-5, and MW-26R, EIC directed the contracted drilling company to use a masonry saw to remove asphalt pavement at each marked location. The driller also conducted an excavation within the underlying soil beneath the pavement in order to locate these wells. Additionally, EIC directed the drilling company to attempt to locate well IW-13 in Tank Farm # 2 utilizing a skid-steer excavator. The aggregate was removed to the depth of an existing geo-synthetic liner and then the aggregate was returned. During this process, care was taken to prevent damage to the geo-synthetic liner. EIC located wells IW-1 and IW-2 via this method. Wells IW-1 and IW-2 were found just under the asphalt pavement and were apparently in a reasonably good condition except that the cast-iron vaults were corroded and the masonry saw damaged the vault lid of well IW-2. The excavations within the paved areas where wells were not located (wells IW-5 and MW-26) were then was backfilled with the earth removed and tamped and the top 6 inches capped with 6-inch thick concrete FTG.

### 3.3.4 Well Abandonment

During EIC's first site mobilization, EIC abandoned wells MW-15 and MW-22R. These wells were abandoned per the Design and Installation of Monitoring wells (SESDGUID-101-R1), in the EPA's Region IV Field Branches Quality System and Technical Procedures document and in accordance with the Water Well Standards Act, O.C.G.A. 12-5-120. The concrete pads surrounding these wells were first removed and disposed of. Then, utilizing a truck-mounted drill rig with 4.25-inch I.D. decontaminated Hollow Stem Augers (H.S.A), well casings were extracted

and the boreholes were over-reamed – removing any remaining well casing. The boreholes were filled with bentonite grout with a tremie pipe. A concrete pad with a thickness of 6 inches was then installed FTG over the grouted hole. Soil cuttings and removed concrete pads were containerized in 55-gallon drums labelled as investigation derived wastes (IDW) for later disposal by VOPAK.

During this mobilization, EIC also initiated the abandonment of well IW-2. This process involved removal of the concrete pad and extraction of 10 feet of solid 1-inch PVC casing (the well screen detached from the solid casing and could not be recovered). The driller then began over-reaming the borehole to remove grout and the remaining well screen with H.S.A. However, at a depth of approximately 3 feet below grade, the auger intercepted an unpressurized 4-inch diameter rhodimet product line causing a rupture. A small volume of rhodimet leaked from the line. Per VOPAK's direction, EIC suspended abandoning this well until VOPAK had cleaned up the rhodimet spill and affected soil. VOPAK then proceeded to clean up the spill and containerize soil removed from around the borehole. VOPAK informed EIC that the abandonment of IW-2 could possibly be completed once the rhodimet line had been fully decommissioned and facility utilities records further reviewed. Due to the possibility of a water main and natural gas line at IW-1, VOPAK directed EIC to terminate abandonment process of that well. As such, EIC left IW-1 in place and capped the saw-cut over IW-1 with concrete FTG. During the initial abandonment of IW-1, only the vault lid was removed.

### 3.3.5 New Well Installations

EIC designed and supervised the installation of three new offsite (approximately 15-foot depth) monitoring wells using the drilling contractor. As discussed in Section 2, these wells were required for complete delineation of the horizontal extent of the CVOC plume.

During the second mobilization, the boreholes for the wells were drilled utilizing a 6620DT GeoProbe with 4.25-inch I.D. decontaminated H.S.A. As per the EPD's comments letter, the first well (named MW-35) was located to the north and down-gradient of MW-27 on Georgia Ports Authority (GPA) property. Additionally, since EIC had determined that certain CVOC contaminant plumes had not been fully delineated north and down-gradient of MW-32 nor south and up-gradient of wells MW-26R and MW-34, two additional wells (named MW-36 and MW-37, respectively) were installed. MW-36 was located to the north of MW-32 on GPA property and MW-37 was located near the un-located MW-28 (on GAF property) to the south of the original CVOC foot-print. Each well was completed in accordance with SESDGUID-101-R1 and O.C.G.A. 12-5-120.

During soil borings for each well, EIC recorded the continuous lithology of soils encountered and the well construction specifications. Figures 3-1 through 3-3 illustrate the as-built well completion logs of wells MW-35, MW-36, and MW-37, respectively, with both lithological and well construction details. EIC also supervised well development of each well to remove fines from the filter-pack, auger and other equipment decontamination procedures, and waste disposal. Soil

cuttings and development water generated was containerized in labeled 55-gallon drums for later disposal by VOPAK. All field activities were recorded in detail on field forms and in a field book.

### 3.3.6 Converting Two Stick-Up Wells to Flush-to-Grade

During the first mobilization, EIC directed the drilling contractor to convert well MW-27 (the well was 4-inches high with no outer protective metal casing) to FTG per SESDGUID-101-R1 and O.C.G.A. 12-5-120. This conversion provides better protection for the well. As such, the drilling contractor cut the 1-inch diameter PVC casing to a level below the ground surface and installed a cast iron well vault with screw-down lid around the PVC casing. A concrete pad was then installed around the vault.

During the second mobilization, per VOPAK's request, EIC converted well LAW-PZ-8R to FTG. This well was originally completed with approximately a 4-foot high stick-up within a protective outer metal casing. As such, EIC utilized the well driller to convert the well to FTG using procedures similar to those used for the MW-27 well conversion. This conversion allows VOPAK to more conveniently load rhodimet product into tanker trucks. The resulting soil and concrete debris were containerized in a labeled 55-gallon drum for later disposal by VOPAK.

### 3.3.7 Survey of New Well Installations and Modified Wells

In January 2014, EIC acquired a land surveyor to survey the three newly installed wells and the two modified wells at the VOPAK Savannah terminal. The geographical survey was conducted, under EIC's supervision, by a professional land surveyor licensed in the State of Georgia.

The primary objectives of the survey were to measure the horizontal and vertical coordinates of the top of casing (TOC) of monitoring wells MW-35 and MW-36 on GPA property and monitoring well MW-37 on GAF property. The surveyor also measured the vertical coordinates of the ground surface adjacent to the three aforementioned wells and the vertical coordinates of the TOC of the two modified wells, LAW-PZ-8R and MW-27 on VOPAK property. Additionally, the surveyor also measured the vertical coordinates of the adjacent ground surface.

#### 3.3.7.1 Field Activities

On January 20, 2014, EIC retained EMC Engineering Services, Inc. (EMC) to conduct the required surveying service. All survey points were referenced to horizontal state plane coordinates of North American Datum (NAD) 83 and vertical elevation coordinates of the National Geodetic Vertical Datum (NGVD) 29 and the North American Vertical Datum (NAVD) 88.

When the surveyor field crew arrived at the site, EIC identified the two wells on VOPAK property that had been converted to flush-to-grade. The surveyors collected the vertical coordinates of the TOCs of these two wells and marked a reference point with a black permanent marker on the TOC. The surveyors then measured the vertical coordinates of the ground surface

adjacent to the two wells. EIC ensured that the surveyors marked the "ground surface" at a point around the pad perimeter approximately midway between the highest and lowest ground surface elevation. The coordinates of LAW-PZ-8R and MW-27 were both successfully collected.

The surveyor then proceeded to collect the horizontal and vertical coordinates of the TOCs of wells MW-35, MW-36, and MW-37 and the ground surface elevation adjacent to each of these wells. A reference point was marked on each TOC of each well to enable well gauging from a consistent location. The coordinates of MW-35 were collected using a GPS system and the established benchmark was referenced for wells MW-36 and MW-37.

After completion of the aforementioned tasks, the surveyor assisted in locating monitoring well MW-31. MW-31 had been buried under stockpiled aggregate related to nearby construction and its exact location was unknown. Utilizing a magnetometer and direction from EIC, EMC quickly pinpointed the exact location of MW-31. EIC then uncovered this well.

#### 3.3.7.2 Basemap Revisions

EMC utilized the newly acquired field data, a historical AutoCAD map prepared by EMC of a previous survey of September 24, 2004, and a current site AutoCAD base map provided to EIC in 2011 to update the current map and depict the locations and coordinates of the surveyed wells. EMC then provided EIC a draft drawing that included horizontal and vertical coordinates in both NGVD 29 and NAVD 88 datums to assist in the update process. After EIC's review and comments, EMC's licensed surveyor signed and stamped hardcopies of the final drawing and data table and mailed them to EIC (Attachment A).

SECTION

4

# 4. QUARTERLY MONITORING

The two quarterly sampling events documented in this section were conducted in fourth quarter of 2013 and first quarter of 2014. The sampling events entailed the collection of groundwater samples for analysis from wells within the previously established area of concern with constituents of concern (COC) including dissolved chlorinated volatile organic compounds (CVOCs) and volatile organic compounds (VOCs) contamination. Under the approved VIRP, all available monitoring wells plus a selected former injection well within and adjacent to the PCE/BTEX contaminant plume are being utilized for the monitored natural attenuation (MNA) remedial approach. The following subsections describe the first quarterly monitoring program for 2014.

## 4.1 GROUNDWATER MONITORING FIELD PROGRAM

During the 2013 fourth quarterly monitoring event that occurred in October 2013, EIC conducted groundwater monitoring at 17 shallow monitoring wells, one shallow injection well, and one deep monitoring well. Prior to sampling, the deep monitoring well (MW-14) was redeveloped as it had not been purged/sampled since September 2009. During the 2013 fourth quarterly groundwater monitoring event, the following wells were utilized for groundwater sampling: LAW-PZ-8R, PAN-MW-9, PAN-MW-10, MW-16, MW-17R, IW-18, MW-14, MW-18R, MW-19, MW-23, MW-24R, MW-25, MW-26R, MW-27, MW-29, MW-30, MW-32, MW-33, and MW-34. During 2014 first quarterly groundwater monitoring event, in addition to these wells, newly available wells MW-35, MW-36, and MW-37 were also utilized for groundwater sampling as well as MW-31, which was inaccessible during the 2013 fourth quarterly event. The site layout is illustrated in Figure 4-1.

### 4.1.1 Sampling Protocol

The groundwater sampling program was conducted in accordance with the current U.S. EPA groundwater sampling procedure "Field Branches Quality System and Technical Procedures" (FBQSTP) per EPD regulations. Each monitoring well was gauged, purged, and sampled following the "low-flow" purge technique established in the standard operating procedure (SOP) SESDPROC-301-R3 under the FBQSTP (EPA, 2013).

### 4.1.2 Site Access

Prior to EIC's site visit, EIC coordinated with the GPA and GAF in gaining access during the two sampling events to collect groundwater samples from a total of six off-site monitoring wells MW-17R, MW-32, MW-34 MW-35, MW-36, and MW-37. Monitoring well MW-37 is located on GAF property and wells MW-17R, MW-32, MW-34, MW-35, and MW-36 are located on GPA property.

### 4.1.3 Field Procedures

#### 4.1.3.1 Groundwater Gauging

Prior to sampling, EIC gauged each well with a Solinst Model 122 interface meter ("oil/water interface probe") to determine the static depth to groundwater. EIC utilized top-of-casing (TOC) elevations from the most recent well surveys to determine the current groundwater elevations. The gauging data for the October 2013 and January 2014 monitoring events are tabulated in Tables 4-1 and 4-2, respectively.

#### 4.1.3.2 Groundwater Sampling

Prior to initiating field sampling activities, EIC obtained 55-gallon drums from VOPAK to containerize purged groundwater. At each wellhead, EIC monitored VOCs air concentrations in parts per million (ppm) with a calibrated photoionization detector. A total of three measurements were taken at the respective well to document VOC concentrations in the ambient air within two feet of and outside the outer well casing, air between the inner well casing and the outer protective casing or vault, and air within the inner well casing. The VOC concentrations observed during the fourth quarter of 2013 were recorded on EIC's October 2013 "Well Purging and Sampling Data field logs" (Attachment B). Due to a malfunction of EIC's photoionization detector during the first quarter of 2014, it was not possible to collect VOC air concentration data for each well. However, any noticeable odors detected were noted on the January 2014 Well Purging and Sampling Data field logs (Attachment C).

EIC utilized a peristaltic pump for purging and sampling. Dedicated disposable 1/4-inch inner diameter and 3/8-inch outer diameter Teflon-lined tubing was utilized at all wells for purging. The well purging data for October 2013 and January 2014 is tabulated in Table 4-3 and Table 4-4, respectively. Groundwater from each monitoring well was pumped via the peristaltic pump through a multi-parameter field water quality meter equipped with a flow-through cell. Following the SOP, SESDPROC-301-R3, EIC set the tubing intake at the center of the wetted screen interval. The tubing was incrementally lowered below this depth if the water level dropped to the depth of the intake during pumping.

After purging began and prior to sampling at each well, water quality parameters, including temperature, pH, oxidation-reduction potential (ORP), specific conductivity, turbidity, dissolved oxygen (DO); rate of evacuation; and depth to water were measured at approximately 5-minute

intervals until certain parameters stabilized per SESDPROC-301-R3. EIC considered that parameters were stabilized when 3 consecutive readings were within ± 0.1 for pH and ± 5% for specific conductivity. Reasonable attempts were made for each well to reach 0.2 mg/L DO and a turbidity reading below 10 Nephelometric Turbidity Units (NTUs). These measurements were recorded on EIC's Well Purging and Sampling Data field logs. Groundwater quality field parameters after stabilization and prior to sample collection are summarized in Table 4-5 and Table 4-6 for October 2013 and January 2014, respectively. The historical natural attenuation parameters recorded during each monitoring event including pH, Temperature, DO, conductivity, and ORP are tabulated in Table 4-7.

After water quality parameters had either stabilized or reasonable attempts had been made to reach stabilization at each accessible well, EIC collected groundwater samples utilizing the "soda straw method", per SESDPROC-301-R3, whereby the Teflon-lined tubing was removed from the well, the peristaltic pump run in reverse, and sample bottles filled from the tubing. To ensure that no groundwater from or beyond the peristaltic pump head reached the sample bottles during sample collection, EIC utilized a minimum of 20 feet of tubing from the pump head. All sample bottles were properly sealed and labeled in the field. Each sample set was then stored with ice in insulated cooler containers provided by the laboratory. Completed chain of custody forms accompanied all samples.

EIC scheduled Xenco Laboratories, a Georgia-certified laboratory located in Norcross, Georgia, to pick up both sets of samples the day after returning to EIC headquarters from the site. The laboratory conducted analysis of volatile organic compounds via EPA method 8260B. The laboratory reports for the October 2013 and January 2014 events are included as Attachment D and Attachment E, respectively.

The 55-gallon drums used for containerization of purge water were placed on the west shoulder of the road between Tank Farm #2 and Tank Farm #3. EIC placed a non-hazardous waste label on each drum and marked the contents as investigative derived waste ("IDW") well purge water and marked the respective accumulation dates. The drums were later disposed of by VOPAK.

#### 4.1.3.3 Deep Monitoring Well MW-14 Redevelopment

Since monitoring well MW-14 was considered a deep well, EIC utilized that well to vertically delineate the CVOC and VOC plumes. Based on actual measurement conducted in January 2013, EIC determined that the total depth of MW-14 was 49.57 feet below top-of-casing. This measurement was consistent with historical well construction data that listed the well as having a total depth of 49.44 feet below grade. The screened interval was reportedly located from 39.44 to 49.44 feet below grade.

Since historical records indicated that MW-14 had not been sampled since September 2009, EIC chose to develop the well prior to sampling. On October 1, 2013, EIC developed MW-14 utilizing a decontaminated submersible pump. Purging was accomplished by pumping the well

water while repeatedly raising and lowering the pump through the entire water column ("surged"). This procedure was performed in an attempt to clean the well screen of stagnant water, accumulated silt, bacteria, minerals, and other deposits. Initially the purge water appeared cloudy with black particulate matter but gradually became clear through the surging process. Approximately 23.5 gallons (3 well volumes) of water were purged from MW-14 during the development procedure.

All purge water was pumped into 5 gallon buckets and then transferred into the 55-gallon drum provided by VOPAK. In accordance with Design and Installation of Monitoring wells (SESDGUID-101-R1) procedure discussed in EPA's Region IV document titled Field Branches Quality System and Technical Procedures, EIC allowed the well to stabilize for a minimum of 24 hours before sampling the well. EIC sampled MW-14 two days later on October 3 as documented on the data field form (Attachment B).

## 4.2 QUALITY ASSURANCE AND QUALITY CONTROL

For groundwater quality assurance and quality control purposes, EIC placed one lab-supplied trip blank set with in each cooler that was used for storage of sample containers with ice. The trip blanks were submitted to the laboratory for analysis via EPA Method 8260B

To prevent cross-contamination, disposable 1/4-inch inner diameter and 3/8-inch outer diameter Teflon-lined tubing was used to collect samples at each well. The dedicated tubing was discarded after each respective well was sampled. EIC's oil/water interface meter, 2000 mL cylinder, and tubing cutter were field decontaminated prior to use and between sample locations by washing with a phosphate-free detergent solution and rinsing with pressurized de-ionized (DI) water. After each sample was collected, the water quality parameters instrument was also decontaminated with DI water.

## 4.3 DATA EVALUATION

EIC conducted an evaluation of the data compiled from field measurements and laboratory analyses to determine the groundwater potentiometric surface and the horizontal and vertical extent of the prevailing contaminant plumes at the time of the October 2013 and January 2014 monitoring events. Data from the sampling events were compared with the data from the baseline and each of the seven subsequent quarterly sampling events to determine if monitored natural attenuation is in process at the site and is likely to lead to remedial end points.

### 4.3.1 Groundwater Potentiometric Map

From the gauging data in Tables 4-1 and 4-2, EIC prepared a groundwater potentiometric surface map for each of the October 2013 and January 2014 quarterly monitoring events, respectively. The groundwater potentiometric surface occurring during the 2013 fourth quarterly and 2014 first quarterly monitoring events are illustrated in Figures 4-2 and 4-3, respectively. EIC compared

these two potentiometric surface maps with the previous eight potentiometric surface maps prepared since the inception of the VIRP in 2011. All ten maps illustrate that the predominant direction of groundwater flow in the area (including the COC foot-print) is due north or north-northeast.

The addition of January 2014 groundwater elevation data from the newly installed monitoring wells MW-35, MW-36, and MW-37 did not result in a significant change in the overall groundwater potentiometric surface or the direction of flow observed over the past nine events. Moreover, this data was consistent with previous data and allowed a depiction of the surface over a wider area to the south and north.

A trough feature of the potentiometric surface lies in the vicinity of Tank Farm # 2 that is oriented parallel to the groundwater flow. Also, a ridge feature of the potentiometric surface along the east of and parallel to the trough feature was once again observed during the October 2013 and January 2014 events. Referring to Figure 4-2, the up-gradient portion of the ridge feature observed during the previous five monitoring events appears to be better defined to the south and aligned further east than in previous events. The addition of groundwater elevation data from new monitoring wells MW-35 and MW-36 also supports the presence of a trough depicted in previous monitoring events. As illustrated in Figure 4-3, it appears that the trough extends northward from the vicinity of former injection well IW-18 to Tank 35 where it then turns towards the northeast and MW-36.

The elevation of the groundwater potentiometric surface did not change significantly between the fourth quarter of 2013 and the first quarter of 2014, however, in general, the groundwater elevation was slightly higher in January 2014. The groundwater elevation in monitoring well MW-27, located in the northeast area of the potentiometric surface depicted, increased by only 0.03 feet from October 2013 to January 2014. The largest increase in elevation in the southern portion of the potentiometric surface was observed at monitoring well MW-26R, where it increased 0.54 feet between the two events.

### 4.3.2 Horizontal Extent of Contaminant Plumes

The analytical data from the October 2013, January 2014, as well as historical analytical data are tabulated in Table 4-8. The COC results for each well sampled during the 2013 fourth quarterly and 2014 first quarterly monitoring events are illustrated in Figures 4-4 and 4-5, respectively. All parameters that exceeded the revised Site Specific Type 4 risk reduction standards (RRS) are shown in red. The following subsections include discussions on the characteristics of each constituent plume relative to historical plume characteristics.

#### 4.3.2.1 CVOC Plume

The CVOCs of concern at the site are tetrachloroethene or perchloroethene (PCE), trichloroethene (TCE), cis-1, 2 dichloroethene (DCE), and vinyl chloride (VC). Figures 4-6

through 4-13 illustrate the horizontal extent of the four CVOC constituent plumes observed in October 2013 and January 2014. In preparing the plume maps, EIC utilized the same contour intervals as those illustrated in the CAP for relative comparison. In addition, the limits of the RRS concentrations and the delineation criterion are illustrated to evaluate the extent of dissolved CVOCs that require remediation and the horizontal extent of the overall plume.

PCE and all three daughter products were detected at MW-37 when this well was first sampled in January 2014. From the 2014 second quarterly monitoring event, EIC will reconfirm the presence and concentration of CVOCs.

**PCE Plume:**

Referring to Figure 4-6, by the October 2013 monitoring event, the PCE concentrations at MW-33 had decreased from 15 µg/L in July 2013 to 1.2 µg/L. This decrease resulted in the PCE plume bisecting to form two separate PCE plumes of similar horizontal extent. The PCE concentration at MW-33 continued to decrease to below detection limits by the January 2014 event, as shown in Figure 4-7.

The highest concentration of PCE within the first PCE plume located in the southern portion of the original CVOC foot-print has remained relatively consistent at LAW-PZ-8R. This concentration has decreased only slightly from 44 µg/L, during the October 2013 monitoring event, to 38 µg/L during the January 2014 monitoring event. However, the horizontal extent of the up-gradient plume is depicted has having increased up-gradient due to additional data indicating PCE at a concentration of 30 µg/L at monitoring well MW-37. This PCE concentration at MW-37 remains unverified pending the next quarterly sampling event.

The highest concentration of PCE in the farthest down-gradient plume occurs at MW-32 as it has during each of the previous sampling events beginning in July 2012. This concentration has increased from 2,200 µg/L, during the July 2013 monitoring event, to 6,200 µg/L and 6,500 µg/L during the October 2013 and January 2014 events, respectively. The down-gradient plume shape indicates that the PCE plume is essentially aligned along the same direction as groundwater flow.

In summary, the overall horizontal extent of the prevailing PCE plume is shrinking in comparison to that of previous monitoring events. However, the current peak PCE concentration at MW-32 has increased significantly in comparison to the July 2013 peak PCE concentration.

In comparing the October 2013 and January 2014 sampling events to the eight previous sampling events (Figures 4-8 through 4-13), EIC observed spatial and temporal variations of the following PCE degradation products.

**TCE Plume:**

Referring to Figure 4-8, the location of the highest concentration of the TCE plume increased from 790 µg/L at well PAN-MW-9 in July 2013 to 1,300 µg/L at well MW-32 in October 2013. This concentration at MW-32 remained at 1,300 µg/L by January 2014, as shown in Figure 4-9. At the time of the January 2014 monitoring event, in addition to that at MW-32, TCE concentrations occurred above the RRS Type 4 standard of 38 µg/L at MW-29 (110 µg/L) and PAN-MW-9 (300 µg/L). In comparison to the July 2013 monitoring event, the TCE concentration at MW-29 has decreased slightly from 69 µg/L to 66 µg/L and the concentration at PAN-MW-9 has decreased by almost half from 790 µg/L to 440 µg/L.

With the addition of well MW-37 to the well monitoring network, the horizontal extent of the TCE plume has been further defined extending hydraulically up-gradient of the original CVOC foot-print. The western edge of the 5 µg/L delineation criterion limit of the TCE plume has shifted approximately 50 feet to the east due to the TCE concentration at well LAW-PZ-8R having decreased to below detection limits by the January 2014 event.

**DCE Plume:**

Referring to Figures 4-10 and 4-11, the highest concentrations of the DCE plume were 8,500 µg/L and 7,200 µg/L (both occurring at well LAW-PZ-8R) during the October 2013 and January 2014 monitoring events, respectively. This is a significant decrease from a concentration of 11,000 µg/L observed at LAW-PZ-8R during the July 2013 monitoring event. The DCE concentration increased most significantly at well MW-29. Between the July 2013 and October 2013 event, the DCE concentration increased at well MW-29 from 2,800 µg/L to 6,100 µg/L. The concentration then slightly decreased at this well to 5,900 µg/L by the January 2014 event.

As with the PCE and TCE plumes, the addition of data from well MW-37 has altered the shape of the DCE plume, extending it further up-gradient than previously depicted. The peak concentration of DCE in the plume (in the vicinity of LAW-PZ-8R and IW-18) to the south of the original CVOC foot-print slightly decreased between the October 2013 and January 2014 events and the north down-gradient peaks of the plume (in the vicinity of MW-29 and PAN-MW-9) slightly increased between the same two events. This shift in concentrations of DCE indicates that PCE natural attenuation is in progress and that the source is diminishing.

In summary, both the highest concentration and the overall horizontal extent of the DCE plume (except to the southeast of LAW-PZ-8R) has significantly decreased in comparison to the October 2011 baseline monitoring event, indicating that the plume is shrinking.

**VC Plume:**

Referring to Figures 4-12 and 4-13, the highest concentration of VC has shifted from LAW-PZ-8R (830 µg/L) in October 2013 to IW-18 (1,900 µg/L) in January 2014. However, the VC

concentration at LAW-PZ-8R did increase from 830 µg/L in October 2013 to 980 µg/L in January 2014. This is slightly lower than the 990 µg/L observed at LAW-PZ-8R in July 2013. Also, the extent of the hydraulically up-gradient portion of the plume has been further defined to the southeast of LAW-PZ-8R with VC apparently occurring at well MW-37 at a concentration of 130 µg/L. The extent of the down-gradient portion of the plume has increased with higher concentrations occurring at wells MW-16, MW-27, MW-29, MW-32, and PAN-MW-9 during the January 2014 event than occurred during the October 2013 event. However, between the October 2013 and January 2014 events, the VC concentrations at wells MW-24R, MW-30, and MW-33 decreased, causing the middle portion of the plume to recede inward. Comparing the January 2014 down-gradient plume to the July 2013 down-gradient plume, it appears that VC plume is extending east because concentrations have decreased in MW-27 and MW-24R and increased in PAN-MW-9 and MW-32.

In summary, both the highest concentration and the overall horizontal extent of the VC plume has increased in comparison to more recent monitoring events. This is a further indication that natural attenuation is occurring.

#### 4.3.2.2 VOC Plume

The VOCs of concern at the site are benzene, toluene, ethylbenzene, and total xylenes (BTEX). Figures 4-14 through 4-21 illustrate the horizontal extent of the VOC plumes at the site during October 2013 and January 2014. In preparing these plume maps, EIC utilized the same contour intervals as those illustrated in the CVOC maps. This allows for a relative comparison of the plume maps between VOC and CVOC limits. Also, the limits of the RRS concentrations and the delineation criterion are illustrated to evaluate the extent of dissolved VOCs that may require remediation. In reviewing these figures, EIC made the following observations:

**Benzene Plume:**

Referring to Figures 4-14 and 4-15, which depict the horizontal extent of the benzene plume during the October 2013 and January 2014 monitoring events, respectively, since July 2013 the plume has remained split into two separate plumes. The peak concentration of the primary benzene plume that lies hydraulically up-gradient in the vicinity of LAW-PZ-8R, has decreased from 1,900 µg/L in July 2013 to 1,500 µg/L during the July 2013 monitoring event and again decreased to 1,200 µg/L during the January 2014 monitoring event. The January 2014 peak concentration is the lowest peak benzene concentration recorded since VIRP monitoring began in October 2011. The down-gradient plume, located in the vicinity of wells MW-24R and MW-29, had a peak concentration of 23 µg/L at MW-29 in January 2014. This is the highest concentration recorded in the down-gradient plume since VIRP monitoring activities began in October 2011.

As with the CVOC plumes, the addition of benzene concentration from new well MW-37 has redefined the extent of the up-gradient benzene plume to expand towards the southeast.

However, this extent will be verified in the next sampling event. In summary, the overall horizontal extent of the benzene plumes have significantly decreased in comparison to the October 2011 baseline monitoring event, indicating that the plumes are shrinking.

**Toluene Plume:**

Referring to Figures 4-16 and 4-17, which depict the horizontal extent of the toluene plume during the October 2013 and January 2014 monitoring events, respectively, since July 2013 the horizontal extent of the toluene plume has decreased slightly. Also, the peak concentration at LAW-PZ-8R decreased from 650 µg/L in July 2013 to 510 µg/L by the October 2013 monitoring event and decreased again to 350 µg/L by January 2014. Both the October 2013 and January 2014 concentrations were the lowest concentrations recorded since VIRP monitoring began in October 2011.

In summary, both the highest concentration and the overall horizontal extent of the toluene plume has significantly decreased in comparison to the October 2011 baseline monitoring event indicating that the plume is shrinking. Additionally, the toluene plume continues to remain below both the RRS and delineation criterion, as it has since July 2012, indicating complete attenuation.

**Ethylbenzene Plume:**

Figures 4-18 and 4-19 depict the ethylbenzene plume separated into two plumes centered on wells LAW-PZ-8R and between wells PAN-MW-9 and MW-29 during October 2013 and January 2014, respectively. Historically, the highest concentration has been at LAW-PZ-8R. However, as of January 2014 the concentration at this well had decreased from 7,600 µg/L in July 2013 to 4000 µg/L. Simultaneously, the concentration at MW-29 increased from 800 µg/L in July 2013 to 1,200 µg/L in October 2013 and again to 3,100 µg/L in January 2014. The 3,100 µg/L concentration is the highest concentration ever recorded at MW-29 since October 2011. The concentration at PAN-MW-9 also increased from 760 µg/L in July 2013 to 1,000 µg/L by January 2014.

In summary, the extent and concentration of the up-gradient plume appears to be decreasing while the extent and concentration of the down-gradient plume is increasing significantly.

**Total Xylenes Plume:**

Figures 4-20 and 4-21 depict the total xylenes plume during October 2013 and January 2014, respectively. As it has since July 2012, the total xylenes plume continues to consist of two separate plumes with the predominant up-gradient plume centered at well LAW-PZ-8R and the down-gradient plume centered between wells PAN-MW-9 and MW-29, similar to the ethylbenzene plume.

The primary peak concentration at LAW-PZ-8R remained constant at 110,000 µg/L from the April 2013 monitoring event until the October 2013 event. By January 2014, the concentration

dropped significantly to 88,000 µg/L, reversing an upward trend observed since October 2012 and the lowest concentration since January 2012. However, the peak concentration of the down-gradient plume has increased by 4,900 µg/L at MW-29 since July 2013 reaching 6,600 µg/L in January 2014. The concentration at PAN-MW-9 increased slightly by 400 µg/L between July and October 2013 and then increased again by another 100 µg/L in January 2014, reaching a concentration of 2,700 µg/L.

In summary, it appears that the extent of the two plumes of the total xylenes plume have remained relatively stable with a slight decrease of the up-gradient plume and a slight increase of the down-gradient plume. It is pertinent that the total xylene concentration is above the RRS level only at well LAW-PZ-8.

### 4.3.3 Vertical Extent of COC Plumes

As discussed in Section 4.1.3.3, monitoring well MW-14 was redeveloped during the October 2013 monitoring event. MW-14 is the only known remaining deep well within the COC footprint, as monitoring well MW-15 has now been abandoned, as discussed in Section 3. After MW-14 was redeveloped it was sampled in October 2013, for the first time since September 2009 and then again in January 2014. As shown in Table 4-8, all monitored COC were below detection limits during both events at well MW-14 with the exception of toluene at 3.5 µg/L in October 2013 – however this was well below RRS. MW-14 will continue to be included in the monitoring program but it appears that vertical delineation of the plume has been completed.

### 4.3.4 Plume Stability

#### 4.3.4.1 CVOC Plume

As discussed in Section 4.3.2.1, since VIRP monitoring was initiated in October 2011, the total CVOC plumes have either split into two separate up-gradient and down-gradient plumes or, have narrowed at the center indicating that the plumes are in the process of splitting into two plumes. Overall, the CVOC plumes appear to be stationary and reducing in concentration and size, as indicated by surrounding wells with concentrations below detection limits and/or below the RRS indicating that all of the CVOC plumes are shrinking. An isolated VC plume, however, remains persistent in the area of MW-16.

Additional January 2014 analytical data from the newly installed wells MW-35 and MW-36 located down-gradient of the CVOC plumes confirmed that all CVOCs were below detection limits at these wells, thereby completing the horizontal delineation of each CVOC plume down-gradient of the original CVOC foot-print. It is pertinent to note that, accordingly, the VC plume has now been fully delineated down-gradient of MW-27.

The January 2014 analytical data from the newly installed well MW-37 located up-gradient of the CVOC plumes, however, indicates that the four CVOC plumes potentially extends up-gradient of

the original CVOC foot-print- from LAW-PZ-8R and onto GAF property. However, as discussed in Section 5.2.1, these results will be reconfirmed after the next sampling event.

#### 4.3.4.2 VOC Plume

In summary, the prevailing VOC plumes appear to be naturally attenuating compared to baseline conditions established in October 2011 and trending towards the established RRS. It is pertinent to note that additional January 2014 analytical data from the newly installed wells MW-35 and MW-36 located down-gradient of the VOC plumes confirmed that all VOCs were below detection limits at these wells, thereby completing the horizontal delineation of each VOC plume down-gradient of the original VOC foot-print.

Additional analytical data from the newly installed well MW-37 located up-gradient of the VOC plumes has delineated toluene and ethylbenzene up-gradient, as the concentrations of these constituents were below detection limits at MW-37. Analytical results from the MW-37 sample also possibly indicate that the benzene and total xylenes plumes actually extend further up-gradient and towards the southeast from LAW-PZ-8R and onto GAF property. However, delineation of the up-gradient extent of benzene and total xylenes cannot be confirmed until analysis of another sample from MW-37 has been completed.

## 4.4 DETAILED TREND ANALYSIS

In a separate study, EIC will perform a detailed evaluation of the plume stability, mobility, and attenuation rates. In concurrence with EPD, VOPAK will utilize a suitable model to further examine the contaminant flux, rates of degradation, long-range plume stability/reduction, attenuation relative to mass loading, and related processes to reach remedial end points.

SECTION

5

# 5. INDICATOR PARAMETERS

The VIRP proposed monitored natural attenuation (MNA) as a remedy to address the prevailing CVOCs. The plan also outlined certain performance metrics to evaluate the effectiveness of the selected remedy. Spatial and temporal analysis of the COC trends discussed in Section 4 serves as one line of evidence that MNA is effective. EPD, however, requires multiple lines of evidence to demonstrate that the MNA-based remedy is not only effective but sustainable.

Another line of evidence that demonstrates the effectiveness of the MNA program would be a verification of the presence and distribution of geochemical indicators of natural attenuation. To achieve this objective, EIC utilized a down-hole data logger to collect in situ data on various indicator parameters. EIC has successfully completed this task. Explicit discussion on the down-hole MNA indicator parameter evaluation is included in a separate report provided as Appendix A. Considering that the primary indicator parameters such as pH, specific conductivity, ORP, DO, and temperature were close to ideal conditions for reductive dechlorination, the CVOC plume is presently in a favorable environment for natural attenuation.

SECTION

6

# 6. CONCLUSIONS

EIC has addressed EPD comments noted in Section 2. During the last time frame, EIC completed the following objectives pertaining to the well network:

- Located wells IW-1 and IW-2.
- Attempted to locate to the extent possible but did not locate wells IW-5, IW-13, MW-20, MW-21, MW-26, nor MW-28.
- Properly abandoned wells MW-15 and MW-22R.
- Attempted to abandon wells IW-1 and IW-2, however, due to encountering a rhodimet product pipeline at IW-2 and due to the possibility of utilities at IW-1, EIC did not complete the abandonment of IW-2 and left IW-1 in place.
- Installed three new monitoring wells MW-35, MW-36, and MW-37.
- Converted wells MW-27 and LAW-PZ-8R from stick-up to FTG completion.

Based on a trend analysis of the historic monitoring data, the VOC and CVOC plumes appear to be relatively stable or shrinking relative to the baseline sampling event in October 2011. Furthermore, with the addition of two new down-gradient monitoring wells (MW-35 and MW-36) in December 2013, the down-gradient horizontal extent of the COC plumes (above RRS) have been delineated. This also addresses the EPD concern about the extent of VC down-gradient of MW-27. Additionally, the vertical extent of all eight monitored VOC and CVOC plumes above RRS have been delineated.

Analytical results from the groundwater sample collected from a new hydraulically up-gradient well (MW-37 installed in December 2013) has indicated that all four monitored CVOC plumes and the VOC plumes benzene and total xylenes extend further up-gradient and southeast from well LAW-PZ-8R than had previously been depicted prior to the installation of this well. However, until the analytical results of MW-37 are verified during the 2014 second quarterly monitoring event, EIC cannot substantiate this finding.

Evaluation of continuous groundwater monitoring data indicates that the geochemical parameters in the subsurface have favorable conditions for reductive dechlorination of CVOCs. Based on

the trend analysis, it also appears that the VOCs have been cometabolized during the reductive decholorination process.

SECTION 7

# 7. SUMMARY OF HOURS

A monthly summary of hours invoiced for the aforementioned tasks during the period from August 2013 through January 2014 are summarized in Attachment F.

| MW-34 (2) | 10.81 | ND | 3.40 | 7.41 | water appears clear in cyclinder |
| MW-35 (2) | 10.40 | ND | 5.63 | 4.77 | 1/4" of tan bacteria on first pull from well, water was clear after first pull |
| MW-36 (2) | 10.42 | ND | 8.53 | 1.89 | first pull from well is tan in color, no bacteria present, water is tan in cylinder |
| MW-37 (2) | 11.57 | ND | 4.15 | 7.42 | gauged from black mark on high side of TOC, red bacteria was present on probe after DTW reading |

**Notes:**

DTW = Depth to Water below TOC
NA = Not Applicable
NM = Not Measured
ND = Not Detected
*TOC elevations are based on well surveys conducted by EMC Engineering on June 30, 2011, January 24, 2013, and January 20, 2014 and are of the NGVD 29 Datum convention.
** DTW measurements were recorded by EIC from 1/19/2014 to 1/21/2014 prior to purging using a Solinst Oil/Water Interface Meter (probe), Model:122.

**Notes:**

All parameters measurements listed, beginning on October 2011, were recorded after parameters had stablized and prior to sample collection, utilizing a Horiba U-52 water quality measuring device.
NS = Not sampled
NL= Not Located
NU= Located but Not Used due to being silted up
NI = Well Not Yet Installed
LAW-PZ-8 was found damaged during June 2006 sampling event and was not sampled. It was replaced by LAW-PZ-8R on October 9, 2006
MW-17 was replaced by MW-17R on October 10, 2006
MW-26 was replaced by MW-26R on October 9, 2006
*1 MW-14 was located by surveyors on January 24, 2013. To be sampled pending redevelopment
*2 MW-15 was filled with silt above water level and could not be used
*3 IW-18 was ultilized as a replacement for MW-15 on October 2011
*4 MW-20 was not located (possibly paved over)
*5 MW-21 was not located
*6 MW-22 was filled with silt and could not be sampled
*7 MW-27 was not possitively identified but is assumed.
*8 MW-28 was not located
*9 MW-30 was installed as a replacement for MW-21 on April 6, 2011
*10 MW-31 was installed as a replacement on April 28, 2011 for MW-27 and lies approximately where MW-27 had been shown on previous site maps
*11 MW-32 was installed as a replacement for MW-20 on April 25, 2011
*12 MW-33 was installed as a replacement for MW-22 on April 28, 2011
*13 MW-34 was installed as a replacement for MW-28 on April 26, 2011
*14 MW-35, MW-36, MW-37 were installed on December 16 and 17 2013
All data prior to October 2011 tabulated by ERM.

**Notes:**

**110,000** Value exceeds a risk reduction standard
NA = Well not accessible due to nearby construction
NS = Well not sampled
NI = Well not installed
NU = Well not used due to being silted
NL = Well not located
< = less than indicated value
< 5/< 500 = sample was analyzed twice
J = this is an estimated value that is above the method detection limit but below the practical quantitation limit.
The sample denoted MW-10 on 12/18/98 is believed to have been collected from MW-9, I.e. the two samples were mislabeled. This table shows what is believed to be correct.
Risk reduction standard, the higher of the Type 3 or 4 from Table 2 of Risk Reduction Standards dated August 13, 2001
Type 3 or 4 RRS from 2/1/1991 to 4/26/2010 from CAP
RRS beginning on 4/27/2011 from VRP Application

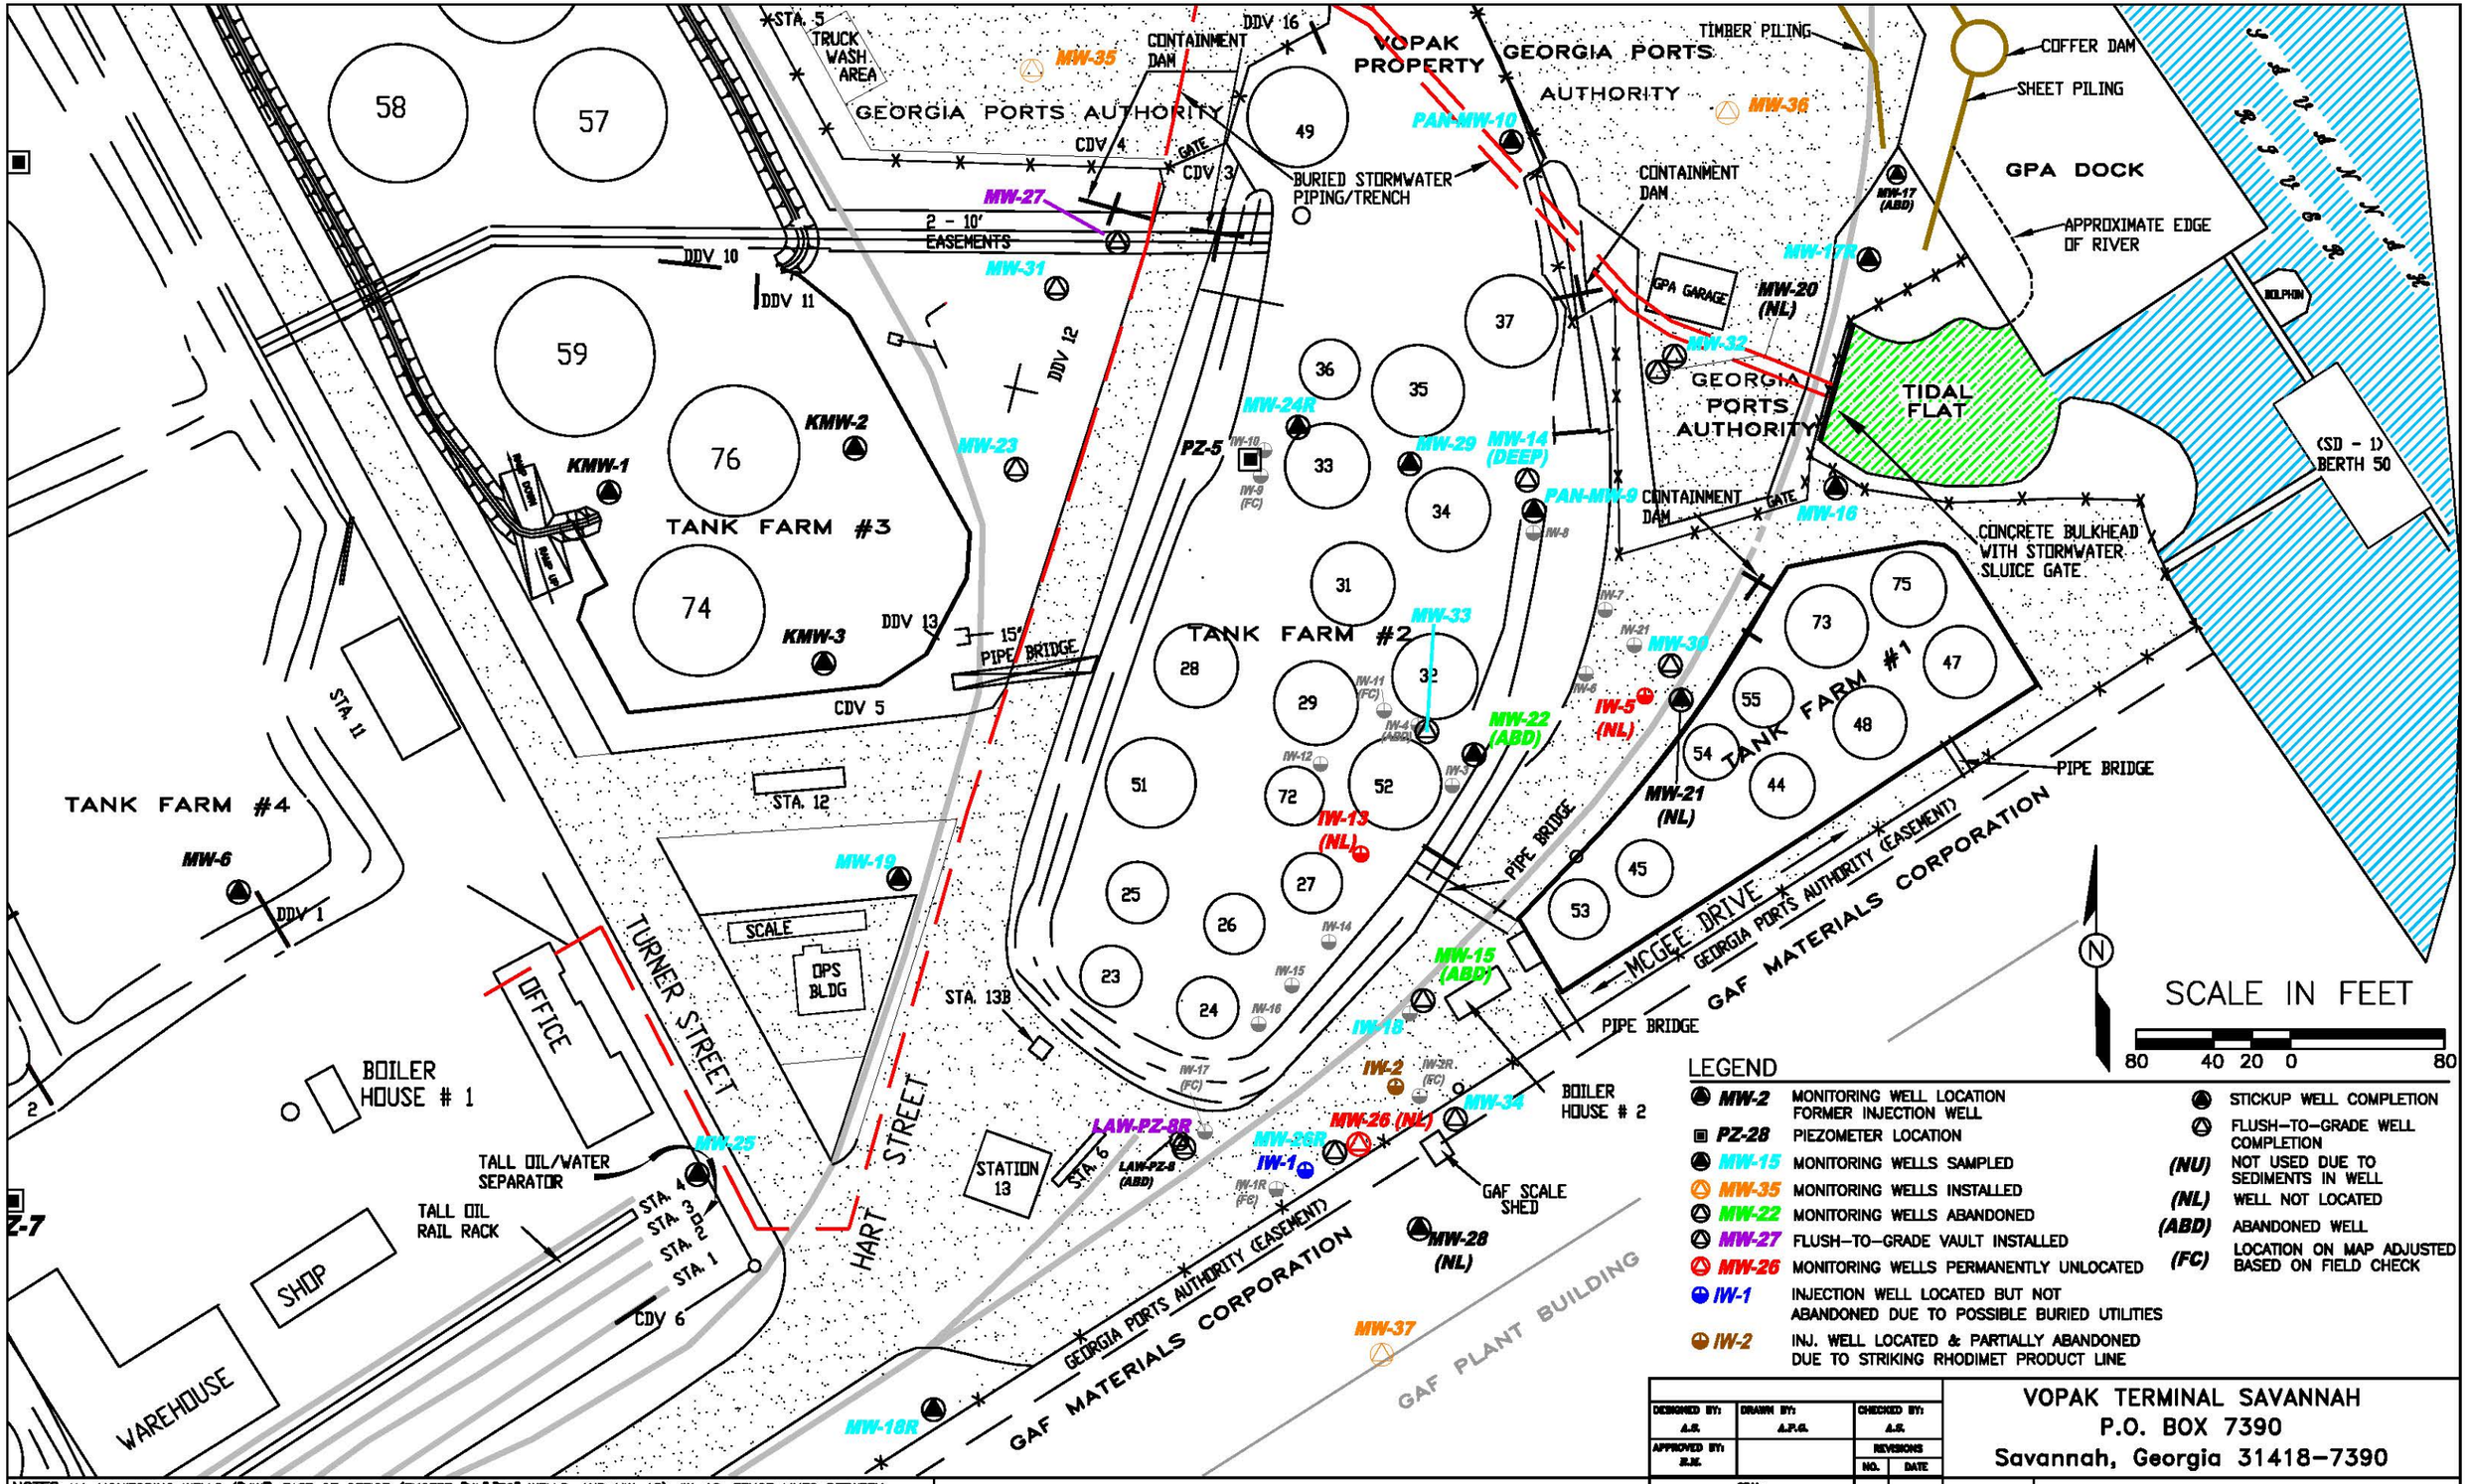
MW-17 was replaced by MW-17R on October 10, 2006
MW-26 was replaced by MW-26R on October 9, 2006
*1 MW-14 was located by surveyors on January 24, 2013. To be sampled pending redevelopment
*2 MW-15 was filled with silt above water level and could not be used
*3 IW-18 was ultilized as a replacement for MW-15
*4 MW-20 was not located (possibly paved over)
*5 MW-21 was not located
*6 MW-22 was filled with silt and could not be sampled
LAW-PZ-8 was found damaged during June 2006 sampling event and was not sampled. It was replaced by LAW-PZ-8R on October 9, 2006
All data prior to October 2011 tabulated by ERM.

*7 MW-27 was not possitively identified but is assumed.
*8 MW-28 was not located
*9 MW-30 was installed as a replacement for MW-21 on April 6, 2011
*10 MW-31 was installed as a replacement on April 28, 2011 for MW-27 and lies approximately where MW-27 had been shown on previous site maps
*11 MW-32 was installed as a replacement for MW-20 on April 25, 2011
*12 MW-33 was installed as a replacement for MW-22 on April 28, 2011
*13 MW-34 was installed as a replacement for MW-28 on April 26, 2011
*14 MW-35, MW-36, and MW-37 were installed December 2013

VOPAK TERMINAL SAVANNAH, SAVANNAH, GEORGIA

# FIFTH SEMIANNUAL PROGRESS REPORT

# FIGURES



LEGEND

| | | | |
|---|---|---|---|
| MW-2 | MONITORING WELL LOCATION FORMER INJECTION WELL | | STICKUP WELL COMPLETION |
| PZ-28 | PIEZOMETER LOCATION | | FLUSH-TO-GRADE WELL COMPLETION |
| MW-15 | MONITORING WELLS SAMPLED | (NU) | NOT USED DUE TO SEDIMENTS IN WELL |
| MW-35 | MONITORING WELLS INSTALLED | (NL) | WELL NOT LOCATED |
| MW-22 | MONITORING WELLS ABANDONED | (ABD) | ABANDONED WELL |
| MW-27 | FLUSH-TO-GRADE VAULT INSTALLED | (FC) | LOCATION ON MAP ADJUSTED BASED ON FIELD CHECK |
| MW-26 | MONITORING WELLS PERMANENTLY UNLOCATED | | |
| IW-1 | INJECTION WELL LOCATED BUT NOT ABANDONED DUE TO POSSIBLE BURIED UTILITIES | | |
| IW-2 | INJ. WELL LOCATED & PARTIALLY ABANDONED DUE TO STRIKING RHODIMET PRODUCT LINE | | |

NOTES: ALL MONITORING WELLS ("MW") EAST OF OFFICE (EXCEPT "NL","FC" WELLS, AND MW-15), IW-18, FENCE LINES BETWEEN VOPAK AND GPA, GPA EASEMENT AND TANKS 32, 34, 37, AND 52 WERE DRAWN BASED ON SURVEY CONDUCTED BY EMC ENGINEERING SERVICES, INC. (EMC) ON 6/30/2011. MONITORING WELLS, MW-14, MW-26R, MW-30, MW-33, AND INJECTION WELLS ("IW") IW2-R, IW5-R, IW-6, IW-7, IW-8, AND IW-21 WERE ADJUSTED BASED ON SURVEY CONDUCTED BY EMC ON 1/24/2013. SHEET PILING, TIMBER PILING, STORMWATER PIPES AND RAIL ROAD FEATURES WERE DRAWN BASED ON AS-BUILT DRAWINGS PROVIDED BY THE GEORGIA PORTS AUTHORITY.
REFERENCE: AUTOCAD BASE MAP MODIFIED FROM ERM REPORT TITLED "2010 VOPAK ANNUAL REPORT ON CORRECTIVE ACTION, HAZARDOUS SITE INVENTORY NUMBER 10464, SAVANNAH GEORGIA"

NOTES: ALL MONITORING WELLS ("MW") EAST OF OFFICE (EXCEPT "NL","FC","KMW" WELLS, AND MW-15), IW-18, FENCE LINES BTWN VOPAK AND GPA, GPA EASEMENT AND TANKS 32, 34, 37, AND 52 WERE DRAWN BASED ON SURVEY CONDUCTED BY EMC ENGINEERING SERVICES, INC. (EMC) ON 6/30/2011. MONITORING WELLS, MW-14, MW-26R, MW-30, MW-33, AND INJECTION WELLS ("IW"), IW2-R, IW5-R, IW-6, IW-7, IW-8, AND IW-21 WERE ADJUSTED BASED ON SURVEY CONDUCTED BY EMC ON 1/24/2013. SHEET PILING, TIMBER PILING, STORMWATER PIPES AND RAIL ROAD FEATURES WERE DRAWN BASED ON AS-BUILT DRAWINGS PROVIDED BY THE GEORGIA PORTS AUTHORITY. THE ABONDONMENT OF IW-2 WAS HALTED IN DEC. 2013 AFTER THE DISCOVERY OF A NEARBY RHODIMET PIPELINE. THEREFORE, IW-2 IS CURRENTLY PARTIALLY ABANDONED. MW-35, MW-36, AND MW-37 WERE PLOTTED BASED ON SURVEY CONDUCTED BY EMC ON 1/20/2014.

(EMC) ON 6/30/2011. MONITORING WELLS, MW-14, MW-26R, MW-30, MW-33, AND INJECTION WELLS ("IW"), IW2-R, IW5-R, IW-6, IW-7, IW-8, AND IW-21 WERE ADJUSTED BASED ON SURVEY CONDUCTED BY EMC ON 1/24/2013. SHEET PILING, TIMBER PILING, STORMWATER PIPES AND RAIL ROAD FEATURES WERE DRAWN BASED ON AS-BUILT DRAWINGS PROVIDED BY THE GEORGIA PORTS AUTHORITY. THE ABONDONMENT OF IW-2 WAS HALTED IN DEC. 2013 AFTER THE DISCOVERY OF A NEARBY RHODIMET PIPELINE. THEREFORE, IW-2 IS CURRENTLY PARTIALLY ABANDONED. MW-35, MW-36, AND MW-37 WERE PLOTTED BASED ON SURVEY CONDUCTED BY EMC ON 1/20/2014.

SHEET PILING, TIMBER PILING, STORMWATER PIPES AND RAIL ROAD FEATURES WERE DRAWN BASED ON AS-BUILT DRAWINGS PROVIDED BY THE GEORGIA PORTS AUTHORITY. THE ABONDONMENT OF IW-2 WAS HALTED IN DEC. 2013 AFTER THE DISCOVERY OF A NEARBY RHODIMET PIPELINE. THEREFORE, IW-2 IS CURRENTLY PARTIALLY ABANDONED. MW-35, MW-36, AND MW-37 WERE PLOTTED BASED ON SURVEY CONDUCTED BY EMC ON 1/20/2014.

COMMENTS: | SAMPLE COLLECTION TIME: 13:20 | PREPARED BY: Patrick Graggen

* Parameters are stabilized when 3 consecutive readings are within ± 0.1 FOR pH and ± 5% for specific conductivity is constant. Reasonable attempts must be made to reach a 0.2 mg/L dissolved oxygen reading and a turbidity reading below 10 NTU as per the Groundwater Sampling Operating Procedure, US EPA, Region 4, # SESDPROC-301-R3.

| | |
|---|---|
| Length of tubing cut (ft.) | 20.0 |
| Initial tubing depth (ft.) BTOC | 11.5 |
| Final tubing depth (ft.) BTOC | 11.5 |
| Initial pump speed | 4.04 |
| Time pump speed was initialized | 12:27 |
| Pump speed at flow into cylinder | 4.04 |
| Started new roll of tubing at | |
| Three well volume (mL) | |

2,000 mL volume poured into bucket:

| Time | 12:45 | 12:58 | 13:15 | | | | | |
|---|---|---|---|---|---|---|---|---|
| Cummulative Volume (mL) | 2000 | 4000 | 6200 | | | | | |

Additional remarks: gauged from black mark on North side of TOC

Very soft bottom when DTB measurement taken. Probe had black, slippery, and gritty substance on tip after DTB, no odor detected

water is gray/black in cylinder
small bubbles on inside of tubing

COMMENTS: SAMPLE COLLECTION TIME: 11:08

PREPARED BY: Patrick Grayson

* Parameters are stabilized when 3 consecutive readings are within ± 0.1 FOR pH and ± 5% for specific conductivity constant.
Reasonable attempts must be made to reach a 0.2 mg/L dissolved oxygen reading and a turbidity reading below 10 NTU as per the Groundwater Sampling Operating Procedure, US EPA, Region 4, # SESDPROC-301-R3.

| | |
|---|---|
| Length of tubing cut (ft.) | 20 |
| Initial tubing depth (ft.) BTOC | ~~5.0~~ 12.0 |
| Final tubing depth (ft.) BTOC | 12.0 |
| Initial pump speed | 4.08 |
| Time pump speed was initialized | 10:40 |
| Pump speed at flow into cylinder | 4.08 |
| Started new roll of tubing at | |
| Three well volume (mL) | |

12:0

Reasonable attempts were made to lower Turbidity below 10 NTUs but due to time constraints, samples were collected

Pump speed slowed due to water level dropping
2260mL 11:00 → 3.53

2,000 mL volume poured into bucket:

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Time | 10:57 | | | | | | | |
| Cummulative Volume (mL) | 2000 | | | | | | | |

Additional remarks: water in cylinder is slightly cloudy w/ a yellowish/tan tint
Orange bacteria on tip of tubing when removed for sampling ~1" cut off
sample bottles have some tan & black bacteria in them

Soft bottom when DTB taken chloride & TDS sample collected

PREPARED BY: Patrick Grayson

* Parameters are stabilized when 3 consecutive readings are within ± 0.1 FOR pH and ± 5% for specific conductivity is constant. Reasonable attempts must be made to reach a 0.2 mg/L dissolved oxygen reading and a turbidity reading below 10 NTU as per the Groundwater Sampling Operating Procedure, US EPA, Region 4, # SESDPROC-301-R3.

| | |
|---|---|
| Length of tubing cut (ft.) | 20 |
| Initial tubing depth (ft.) BTOC | 13.5 |
| Final tubing depth (ft.) BTOC | 13.5 |
| Initial pump speed | 2.48 |
| Time pump speed was initialized | 9:19 |
| Pump speed at flow into cylinder | 2.48 |
| Started new roll of tubing at | |
| Three well volume (mL) | |

Sampled by using new silicon tubing and connecter piece to horiba and then cutting tube ~~that~~ between pump & horiba,
Chloride & TDS samples collected

2,000 mL volume poured into bucket:

| Time | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Cummulative Volume (mL) | | | | | | | | |

Additional remarks: Tidal Water in tidal flat is completely submerging the sluice gate

COMMENTS:

SAMPLE COLLECTION TIME: 12:27

PREPARED BY: Will Grant

* Parameters are stabilized when 3 consecutive readings are within ± 0.1 FOR pH and ± 5% for specific conductivity is constant.

Reasonable attempts must be made to reach a 0.2 mg/L dissolved oxygen reading and a turbidity reading below 10 NTU as per the Groundwater Sampling Operating Procedure, US EPA, Region 4, # SESDPROC-301-R3.

strong background odor of turpentine

COMMENTS:

SAMPLE COLLECTION TIME: 18:21

PREPARED BY: Will Grant

* Parameters are stabilized when 3 consecutive readings are within ± 0.1 FOR pH and ± 5% for specific conductivity is constant. Reasonable attempts must be made to reach a 0.2 mg/L dissolved oxygen reading and a turbidity reading below 10 NTU as per the Groundwater Sampling Operating Procedure, US EPA, Region 4, # SESDPROC-301-R3.

## WELL PURGING AND SAMPLING DATA LOG

WELL/SAMPLE NO: MW-25

DATE: 1/20/19 | PROJECT NAME: VOPAK Savannah | PROJECT NO: 390020

WEATHER CONDITIONS: sunny ~ 53°F, 0-5 mph wind

SAMPLE TYPE: [X] GROUNDWATER [ ] WASTEWATER [ ] SURFACE WATER [ ] OTHER

WELL DIAMETER (IN.) [X] 1 [ ] 2 [ ] 4 [ ] 6 [ ] OTHER | BGS WELL SCREEN INTERVAL: 6.40 FT. to 16.40 FT.

INITIAL WATER LEVEL (BTOC): 6.42 FT. | TIME: 8:53 | BTOC WELL SCREEN INTERVAL: 9.67 FT. to 19.67 FT.

HISTORICAL TOTAL WELL DEPTH (BTOC): 17.93 FT. | MEASURED TOTAL WELL DEPTH (BTOC 17.91 FT. | HEIGHT OF STICK-UP: 3.27 FT.

PURGING DEVICE: Pegasus Alexis Peristaltic Pump [ ] DEDICATED [ ] DISPOSABLE [ ] DECONTAMINATED

SAMPLING DEVICE: 1/4" Teflon lined tubing [ ] DEDICATED [X] DISPOSABLE [ ] DECONTAMINATED

EQUIP. DECON. [X] ALCONOX WASH [ ] ISOPROPANOL [X] DIST/DEION 1 RINSE [ ] DIST/DEION FINAL RINSE [X] AIR DRY

[ ] LIQUINOX WASH [ ] DIST/DEION 2 RINSE [ ] OTHER SOLVENT [ ] TAP WATER WASH [ ] TAP WATER FINAL RINSE

PID/FID READINGS (ppm): BACKGROUND: ND | BENEATH OUTER CAP: ND | BENEATH INNER CAP: ND

CONTAINER PRESERVATION: [X] LAB PRESERVED [ ] FIELD PRESERVED

ANALYTICAL PARAMETERS: 8260 B

LABORATORY PERFORMING ANALYSIS: Xenco | WATER ANALYZER MODEL: Horiba U-52 | SERIAL # UDRU5DA9

| TIME | VOLUME PURGED (mL) | TEMP (°C) | pH | ORP (mV) | SPEC. COND. (mS/cm) | TURBIDITY (NTU) | DISS. OXYGEN. (mg/L) | DTW (FT) | REMARKS (COLOR, ODOR, ETC.) |
|---|---|---|---|---|---|---|---|---|---|
| 9:28 | 0 | 14.12 | 5.98 | 117 | 0.751 | 107 | 5.07 | N/A | first pull is clear, no odor |
| 9:34 | 800 | 15.77 | 6.09 | 59 | 0.788 | 81.8 | 2.70 | N/A | |

| | | | | | | | | 7.15 | |

COMMENTS:

SAMPLE COLLECTION TIME: 10:05

PREPARED BY: Will Grant

* Parameters are stabilized when 3 consecutive readings are within ± 0.1 FOR pH and ± 5% for specific conductivity is constant.

Reasonable attempts must be made to reach a 0.2 mg/L dissolved oxygen reading and a turbidity reading below 10 NTU as per the Groundwater Sampling Operating Procedure, US EPA, Region 4, # SESDPROC-301-R3.

| | |
|---|---|
| Length of tubing cut (ft.) | 20.0 |
| Initial tubing depth (ft.) BTOC | 14.0 |
| Final tubing depth (ft.) BTOC | 14.0 |
| Initial pump speed | 4.04 |
| Time pump speed was initialized | 9:24 |
| Pump speed at flow into cylinder | 4.04 |
| Started new roll of tubing at | — |
| Three well volume (mL) | — |

2,000 mL volume poured into bucket:

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Time | 9:43 | 9:57 | | | | | | |
| Cummulative Volume (mL) | 2000 | 4000 | | | | | | |

Additional remarks: probe has rust/red bacteria after gauging, water is tan + cloudy in cylinder

SAMPLE COLLECTION TIME: 10:43

PREPARED BY: Will Grant

* Parameters are stabilized when 3 consecutive readings are within ± 0.1 FOR pH and ± 5% for specific conductivity is constant. Reasonable attempts must be made to reach a 0.2 mg/L dissolved oxygen reading and a turbidity reading below 10 NTU as per the Groundwater Sampling Operating Procedure, US EPA, Region 4, # SESDPROC-301-R3.

Project Address: GA

**Alan Sanders**:

We are reporting to you the results of the analyses performed on the samples received under the project name referenced above and identified with the XENCO Report Number(s) 471644. All results being reported under this Report Number apply to the samples analyzed and properly identified with a Laboratory ID number. Subcontracted analyses are identified in this report with either the NELAC certification number of the subcontract lab in the analyst ID field, or the complete subcontracted report attached to this report.

Unless otherwise noted in a Case Narrative, all data reported in this Analytical Report are in compliance with NELAC standards. The uncertainty of measurement associated with the results of analysis reported is available upon request. Should insufficient sample be provided to the laboratory to meet the method and NELAC Matrix Duplicate and Matrix Spike requirements, then the data will be analyzed, evaluated and reported using all other available quality control measures.

The validity and integrity of this report will remain intact as long as it is accompanied by this letter and reproduced in full, unless written approval is granted by XENCO Laboratories. This report will be filed for at least 5 years in our archives after which time it will be destroyed without further notice, unless otherwise arranged with you. The samples received, and described as recorded in Report No. 471644 will be filed for 60 days, and after that time they will be properly disposed without further notice, unless otherwise arranged with you. We reserve the right to return to you any unused samples, extracts or solutions related to them if we consider so necessary (e.g., samples identified as hazardous waste, sample sizes exceeding analytical standard practices, controlled substances under regulated protocols, etc).

We thank you for selecting XENCO Laboratories to serve your analytical needs. If you have any questions concerning this report, please feel free to contact us at any time.

Respectfully,

Eben D. Buchanan, Jr.

# Flagging Criteria

**X** In our quality control review of the data a QC deficiency was observed and flagged as noted. MS/MSD recoveries were found to be outside of the laboratory control limits due to possible matrix /chemical interference, or a concentration of target analyte high enough to affect the recovery of the spike concentration. This condition could also affect the relative percent difference in the MS/MSD.

**B** A target analyte or common laboratory contaminant was identified in the method blank. Its presence indicates possible field or laboratory contamination.

**D** The sample(s) were diluted due to targets detected over the highest point of the calibration curve, or due to matrix interference. Dilution factors are included in the final results. The result is from a diluted sample.

**E** The data exceeds the upper calibration limit; therefore, the concentration is reported as estimated.

**F** RPD exceeded lab control limits.

**J** The target analyte was positively identified below the quantiation limit and above the detection limit.

**U** Analyte was not detected.

**L** The LCS data for this analytical batch was reported below the laboratory control limits for this analyte. The department supervisor and QA Director reviewed data. The samples were either reanalyzed or flagged as estimated concentrations.

**H** The LCS data for this analytical batch was reported above the laboratory control limits. Supporting QC Data were reviewed by the Department Supervisor and QA Director. Data were determined to be valid for reporting.

**K** Sample analyzed outside of recommended hold time.

**JN** A combination of the "N" and the "J" qualifier. The analysis indicates that the analyte is "tentatively identified" and the associated numerical value may not be consistent with the amount actually present in the environmental sample.

** Surrogate recovered outside laboratory control limit.

**BRL** Below Reporting Limit.

**RL** Reporting Limit

**MDL** Method Detection Limit **SDL** Sample Detection Limit **LOD** Limit of Detection

**PQL** Practical Quantitation Limit **MQL** Method Quantitation Limit **LOQ** Limit of Quantitation

**DL** Method Detection Limit

**NC** Non-Calculable

\+ NELAC certification not offered for this compound.

***** (Next to analyte name or method description) = Outside XENCO's scope of NELAC accreditation

Reference: XENCO Report No(s): **477891**
**VOPAK-Savannah**
Project Address: GA

**Alan Sanders**:

We are reporting to you the results of the analyses performed on the samples received under the project name referenced above and identified with the XENCO Report Number(s) 477891. All results being reported under this Report Number apply to the samples analyzed and properly identified with a Laboratory ID number. Subcontracted analyses are identified in this report with either the NELAC certification number of the subcontract lab in the analyst ID field, or the complete subcontracted report attached to this report.

Unless otherwise noted in a Case Narrative, all data reported in this Analytical Report are in compliance with NELAC standards. The uncertainty of measurement associated with the results of analysis reported is available upon request. Should insufficient sample be provided to the laboratory to meet the method and NELAC Matrix Duplicate and Matrix Spike requirements, then the data will be analyzed, evaluated and reported using all other available quality control measures.

The validity and integrity of this report will remain intact as long as it is accompanied by this letter and reproduced in full, unless written approval is granted by XENCO Laboratories. This report will be filed for at least 5 years in our archives after which time it will be destroyed without further notice, unless otherwise arranged with you. The samples received, and described as recorded in Report No. 477891 will be filed for 60 days, and after that time they will be properly disposed without further notice, unless otherwise arranged with you. We reserve the right to return to you any unused samples, extracts or solutions related to them if we consider so necessary (e.g., samples identified as hazardous waste, sample sizes exceeding analytical standard practices, controlled substances under regulated protocols, etc).

We thank you for selecting XENCO Laboratories to serve your analytical needs. If you have any questions concerning this report, please feel free to contact us at any time.

Respectfully,

Eben D. Buchanan, Jr.

**Sample receipt non conformances and comments:**

This revised report replaces the report issued on January 31, 2014.
The report was revised to include the dilution analysis of Sample MW-37 (477891-021) for cis-1,2-Dichloroethene.

**Sample receipt non conformances and comments per sample:**

None

**Analytical non conformances and comments:**

Batch: LBA-932992 VOCs by SW-846 8260B
Trichloroethene recovered above QC limits in the Matrix Spike. Bromoform recovered above QC limits in the Matrix Spike Duplicate. Samples affected are: 477891-008.
The Laboratory Control Sample for Trichloroethene, Bromoform is within laboratory Control Limits

Batch: LBA-933016 VOCs by SW-846 8260B
Bromoform, cis-1,3-Dichloropropene recovered above QC limits in the Matrix Spike.
Samples affected are: 477891-023.
The Laboratory Control Sample for cis-1,3-Dichloropropene, Bromoform is within laboratory Control Limits

# Flagging Criteria

**X** In our quality control review of the data a QC deficiency was observed and flagged as noted. MS/MSD recoveries were found to be outside of the laboratory control limits due to possible matrix /chemical interference, or a concentration of target analyte high enough to affect the recovery of the spike concentration. This condition could also affect the relative percent difference in the MS/MSD.

**B** A target analyte or common laboratory contaminant was identified in the method blank. Its presence indicates possible field or laboratory contamination.

**D** The sample(s) were diluted due to targets detected over the highest point of the calibration curve, or due to matrix interference. Dilution factors are included in the final results. The result is from a diluted sample.

**E** The data exceeds the upper calibration limit; therefore, the concentration is reported as estimated.

**F** RPD exceeded lab control limits.

**J** The target analyte was positively identified below the quantitation limit and above the detection limit.

**U** Analyte was not detected.

**L** The LCS data for this analytical batch was reported below the laboratory control limits for this analyte. The department supervisor and QA Director reviewed data. The samples were either reanalyzed or flagged as estimated concentrations.

**H** The LCS data for this analytical batch was reported above the laboratory control limits. Supporting QC Data were reviewed by the Department Supervisor and QA Director. Data were determined to be valid for reporting.

**K** Sample analyzed outside of recommended hold time.

**JN** A combination of the "N" and the "J" qualifier. The analysis indicates that the analyte is "tentatively identified" and the associated numerical value may not be consistent with the amount actually present in the environmental sample.

** Surrogate recovered outside laboratory control limit.

**BRL** Below Reporting Limit.

**RL** Reporting Limit

**MDL** Method Detection Limit **SDL** Sample Detection Limit **LOD** Limit of Detection

**PQL** Practical Quantitation Limit **MQL** Method Quantitation Limit **LOQ** Limit of Quantitation

**DL** Method Detection Limit

**NC** Non-Calculable

+ NELAC certification not offered for this compound.

***** (Next to analyte name or method description) = Outside XENCO's scope of NELAC accreditation

# 1. INTRODUCTION

EIC is pleased to submit this report that documents EIC's evaluation of the potential impact of in situ geochemical indicator parameters on constituents of concern (COC) in groundwater, under the VRP program approved by the Georgia Environmental Protection Division (EPD) to VOPAK Terminal Savannah (VOPAK). The COC consist of volatile organic compounds (VOCs) and chlorinated VOCs (CVOCs). For this evaluation, EIC utilized down-hole multi-parameter data loggers for the continuous real-time collection of water level data and indicator parameters from selected monitoring wells.

DRAFT

## 1.1 PROJECT OBJECTIVES

The primary objective was to collect continuous downhole geochemical water quality data from selected monitoring wells at the VOPAK terminal. The data was used to define the in situ baseline conditions of indicator parameters that are useful in determining whether the site-specific subsurface conditions are favorable for natural attenuation of chlorinated organic constituents. This evaluation also serves as one of the lines of evidence to verify whether MNA is effective and sustainable.

## 1.2 EIC's APPROACH

To conduct this study, EIC utilized down-hole multi-parameter data-loggers that met the well diameter restrictions of monitor wells in the area of the PCE plume. Since the data-loggers required at least a 2-inch diameter well, EIC selected four 2-inch monitoring wells for probe installation. Each data-logger continuously measures temperature, conductivity, dissolved oxygen (DO), pH, oxygen reduction potential (ORP), and other inorganic parameters at pre-programmed time intervals. The data-loggers also measured groundwater levels from pressure transducers within the probes.

EIC strategically selected well locations for the study, based on known plume characteristics and site conditions that provide the most significant data towards determining a remedial strategy. Additional criteria considered included well design, the groundwater potentiometric surface, groundwater flow direction, and locations of the highest COC concentrations. After a one-week period, EIC retrieved the devices and downloaded the data onto a field laptop computer for

analysis. The resulting data was utilized in examining the potential impact of indicator parameters on the natural attenuation of the COCs at the site. The data will also be utilized in a site conceptual model that defines the fluid flow hydrodynamics and contaminant fate and transport conditions.

SECTION

2

# 2. FIELD ACTIVITIES

To accomplish the project goals, EIC conducted various field activities during the week of April 9, 2012. The field activities entailed the installation of multi-parameter probes in select wells. The following subsections describe the field activities.

## 2.1 INSTALLATION OF MULTI-PARAMETER DATA LOGGER

On April 12, 2012, EIC installed continuous data logging devices in four wells identified as PAN-MW-9, MW-31, MW-32, and MW-33 as illustrated in Figure 2-1. Each device was comprised of a pressure transducer and thermometer as well as sensors that measured pH, conductivity, ORP, DO, and temperature.

DRAFT

Prior to the installation of the multi-parameter data loggers, EIC first programmed each device and initiated the data logger using a hand-held multi-parameter display system (MDS) supplied by the transducer manufacturer. EIC connected each device to the MDS via a communication link and programmed all 4 devices to record data at 5 minute intervals, the minimum time interval to log one week of data without exceeding the internal memory of the device.

After programming, EIC strategically installed the 4 multi-parameter data loggers into wells PAN-MW-9, MW-31, MW-32, and MW-33, as illustrated in Figure 2-1. Since PAN-MW-9, MW-32, and MW-33 were located within the CVOC and VOC plumes, EIC chose these wells to monitor the MNA indicator parameters to evaluate the potential for the natural degradation of the COC. MW-31, located outside the horizontal extent of the CVOC and VOC plumes and historically a clean well, was chosen to be a control well for EIC.

The transducers were installed in each well at a height of approximately two feet above the bottom of each well. These depths are tabulated in Table 2-1. EIC selected a height of two feet above the bottom of the well to allow an adequate head of water above the transducer and to ensure constant submersion. Also, the transducer was installed at a sufficient height above the well bottom to prevent silt on the bottom of the well from fouling the sensors of each probe.

Once the devices were lowered into the wells to the proper depths, EIC secured the probes by taping each probe cable to the well TOC and/or the well stickup casing (if available) or to a traffic

cone to ensure that the cable was immobile throughout the test. To further secure the cables at flush-to-grade (FTG) wells, EIC returned the well vault covers on the well vaults so they applied pressure on the cables.

After all devices were initially programmed, installed, and secured; EIC connected the field laptop and hand-held MDS to each data cable, respectively, to conduct a quality assurance quality control (QA/QC) test. EIC was able to confirm that the appropriate measurements were being automatically taken within the set time interval from the pressure-specific transducer and multi-parameter data logger. EIC confirmed that all devices were operating properly as programmed.

## 2.2 RETRIVAL OF DATA LOGGERS

On April 19, 2012, EIC returned to the site and successfully downloaded the data from all devices onto a field laptop. Since the data logging period for the down-hole monitored natural attenuation (MNA) indicator parameters evaluation was complete, EIC retrieved all multi-parameter data loggers from their respective wells and closed and locked these wells. Table 2-2 lists the probe operating schedule. The data downloaded from the multi-parameter probe is included as Attachment A.

DRAFT

SECTION

3

# 3. DATA EVALUATION

EIC tabulated all data collected during the testing interval and then extracted a representative subset of data to remove invalid data that typically occurs during installation and withdrawal of the probes from the well. The duration of the representative data utilized in EIC's analysis begins at 5 pm on April 12, 2012 and terminates at 12 pm on April 19, 2012. Utilizing the subset of data, EIC prepared Figures 3-1 to 3-20. The following sections describe the trends observed for each of the field indicator parameters measured during the testing period.

## 3.1 IDEAL CONDITIONS FOR BIOREMEDIATION

Table 3-1 lists ideal conditions for preliminary screening of certain indicator parameters to metabolize CVOCs under anaerobic conditions (EPA, 1998). EIC prepared Table 3-2 to compare the average values of the indicator parameters monitored in several wells to the ideal conditions to determine whether the prevailing site conditions are favorable to reductive dechlorination.

DRAFT

## 3.2 pH VARIATION

Referring to Figures 3-1 and 3-2, it is apparent that the pH values have remained relatively stable at wells PAN-MW-9 and MW-33, respectively. Both of these wells are located within the original footprint of the CVOC plume. From Figures 3-3 and 3-4 it apparent that the pH in MW-31 and MW-32, respectively, located hydraulically side gradient of the plume, has varied over time.

Referring to Table 3-2, the pH values in all tested wells are near ideal conditions for reductive dechlorination except that the pH at PAN-MW-9 is slightly acidic. These values represent typical groundwater conditions conducive to biodegradation processes. According to Vainberg, et al (2006), the optimal pH for microbially induced dechlorination is 5.5 to 7.5 units. Therefore, some pH enhancement may be required at PAN-MW-9 and MW-32 to provide optimal conditions for further attenuation.

## 3.3 SPECIFIC CONDUCTANCE

Referring to Figures 3-5, 3-6, and 3-8, it is apparent that the specific conductivity values have remained relatively stable at wells PAN-MW-9, MW-33, and MW-31, respectively. From Figures

3-7 it is apparent that the pH at MW-32, located hydraulically side gradient of the plume, has varied over time.

Referring to Table 3-2, the average specific conductivity in all wells ranged from 0.53 to 1.25 mS/cm. These values indicate that salinity is relatively low.

## 3.4 ORP

Referring to Figures 3-9 to 3-12, it is apparent that the ORP values declined at all 4 wells during the testing period. The most significant drop was observed at wells MW-33 and MW-32. It is also noteworthy that at MW-31 the ORP values were initially at values greater than zero but gradually declined to below zero values.

Referring to Table 3-2, the average ORP values have remained below 50 millivolts indicating favorable conditions for reductive dechlorination in all four wells. Although the ORP values at MW-31 were not the most favorable for reductive dechlorination, groundwater at MW-31 lies hydraulically sidegradient and outside the original CVOC foot-print. As such, the ORP conditions at MW-31 are irrelevant to the CVOC remediation program.

## 3.5 DISSOLVED OXYGEN

Referring to Figures 3-13 to 3-16, it is apparent that the DO values have remained relatively stable at all four wells. These values indicate that the groundwater at each well is present in an anaerobic environment. Referring to Table 3-2, the average DO values remained below 0.5 mg/L indicating favorable conditions for reductive dechlorination in all four wells.

DRAFT

## 3.6 TEMPERATURE

Referring to Figures 3-17 to 3-20, it is apparent that the temperature values increased slightly at PAN-MW-9, MW-33, and MW-32. The temperature values at MW-31 remained relatively unchanged during the monitoring period.

Referring to Table 3-2, the temperature values have ranged from approximately 19 through 21 Celsius. These values represent typical groundwater conditions conducive to biodegradation processes.

SECTION

4

# 4. CONCLUSIONS

EIC utilized a continuous downhole data logger to successfully collect in situ data on various geochemical indicator parameters. Considering that the primary indicator parameters such as pH, specific conductivity, ORP, DO, and temperature were close to ideal conditions for reductive dechlorination, the CVOC plume is present in a favorable environment for natural attenuation.

According to EPA (1998), reductive dechlorination affects each of the chlorinated ethenes differently. Of these compounds, PCE is the most susceptible to reductive dechlorination because it is the most oxidized. Conversely, VC is the least susceptible to reductive dechlorination because it is the least oxidized of these compounds. Consequently, the rate of reductive dechlorination decreases as the degree of chlorination decreases (Vogel and McCarty, 1985; Bouwer, 1994). According to Murray and Richardson (1993), a gradual decrease in reductive dechlorination may explain the accumulation of VC in PCE and TCE plumes in those environments where reductive dechlorination is in process.

DRAFT

Since chlorinated aliphatic hydrocarbon compounds are used as electron acceptor during reductive dechlorination, an appropriate source of carbon is essential for microbial growth to sustain such processes (Bouwer, 1994). Potential carbon sources include natural organic matter, fuel hydrocarbons, or other anthropogenic organic compounds such as those found in landfill leachate. Although the total organic content was not measured, at the VOPAK site, historic sampling has indicated presence of petroleum hydrocarbons in the CVOC foot-print. Considering that the on-going trend analysis from quarterly monitoring events indicates that both petroleum hydrocarbons and CVOC plumes have steadily decreased in size, it appears that both class of constituents have cometabolized through natural attenuation.

During subsequent monitoring events, EIC plans to collect additional samples to test for alkalinity, ferrous iron, ferric iron, total sulfite, chloride, nitrate, nitrite, sulfate, total iron, methane, ethane, ethene, and related indicator parameters from selected wells within the CVOC foot-print to verify which attenuation processes are dominant. In addition, microcosm testing may be performed to determine whether enhanced attenuation is required to reach remedial end points within the VIRP time frame. Ultimately, however, the actual CVOCs concentrations measured from periodic sampling events substantiate the remedial trend.

In another context, EIC has observed that VC has remained persistent at very low levels in down-gradient locations and, in particular, at MW-16. According to EPA (1998), vinyl chloride can be rapidly oxidized under aerobic conditions. As such, VOPAK is considering localized treatment with aerobic or iron-reduction based techniques unless VC reduces to below RRS standards within the VIRP schedule.

In summary, enhanced attenuation with pH adjustment may be required to optimize the residual PCE and treatment of VC may be required to accelerate its complete metabolism into carbon dioxide and water. The data collected from the current study will be utilized to further refine the site conceptual model. Additional data from microcosm tests, and MNA parameters may be required for further substantiate the natural attenuation process.
