Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

95% Adjusted Gamma UCL 74.36

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

**Groundwater/Surface Water Interactions**

# Groundwater/Surface Water Interactions

---

Part of the support documentation required for renewal of the Resource Conservation and Recovery Act permit for the landfill is as follows:

(1) risk assessment evaluations that include the effects of groundwater discharges from beneath the landfill into Todd Creek; and (2) development of site-specific Todd Creek Target Levels. This evaluation of groundwater/surface water interactions was completed in 2010 as part of the 2011 permit (CH2M 2011).

As part of this permit renewal application the assumptions in 2010 evaluation were reviewed and compared with the currently available data/information to determine if any updates were necessary. There is no new data on the underlying physical characteristics of the aquifer (porosity, effective porosity, and hydraulic conductivity) and there is no new data on surface water flow in Todd Creek; therefore, the assumptions in the 2010 evaluation remain valid. Semi-annual groundwater monitoring has been conducted since the previous evaluation and the groundwater velocity for the aquifer has been calculated for each event. The average reported groundwater velocity for the time period March 2018 through March 2023 was 56 feet/year which is lower than the value of 98 feet/year used in the 2010 evaluation indicating that the 2010 evaluation was more conservative (e.g., a higher groundwater discharge results in less dilution and mixing) than current measurements and therefore the calculations herein were not updated with more recent data. Section E.9d.3.2 provides the risk assessment summary, and Appendix G contains the supporting information.

The Todd Creek Target Level development process included estimating the mixing potential for groundwater seepage into Todd Creek. This section of the revised permit application provides background information on the groundwater–surface water interactions in the vicinity of the landfill and summarizes the approach and process used to estimate a potential range of mixing factors for groundwater discharging into Todd Creek.

## 1. Background and Conceptual Model

Todd Creek is a meandering tidal creek that is hydraulically connected with the Satilla River via Floyd Basin and Floyd Cut (Figure 1). Floyd Cut is connected with Floyd Creek, the southern end of which discharges to the Cumberland River. The Satilla and Cumberland Rivers discharge into a coastal embayment that is part of St. Andrews Sound.

Todd Creek is approximately 300 feet wide with depths up to 25 feet below National Geodetic Vertical Datum in the vicinity of the landfill.

Currents within Todd Creek in the project vicinity are largely driven by tidal action as water levels rise and fall, causing flood and ebb currents with water flowing through the creek channels and over the marsh flats to the north. In addition to astronomical tides, sudden increases in water levels, called storm surges, can occur during passage of significant storms. To a lesser extent, surface water runoff and groundwater seepage into Todd Creek results in a riverine component of the current flowing out toward the mouth of the creek.

Groundwater that seeps into Todd Creek is transported via advection with currents (both tidal and riverine) and dispersion through a number of dispersive mechanisms such as shear flow dispersion, tidal trapping, and mixing and density effects caused by freshwater inflows. Tidal currents average to a net zero flow over time, so for the purposes of calculating buildup of groundwater in the river over time, tidal current

velocities are neglected; however, their effects can be accounted for by appropriately selected longitudinal dispersion coefficients. Riverine currents are caused by any freshwater flows into the creek (e.g., runoff, groundwater discharge) and affect mixing of the groundwater discharges from beneath the landfill area by increasing the net flow past the site and advecting the discharges away, resulting in less buildup of groundwater at the site. To give a conservative mixing factor, in this analysis it was assumed that groundwater flow from beneath the landfill site is the sole source of riverine flow in Todd Creek.

A steady-state approach similar to the “salt balance” concept for salinity levels in an estuary presented in Fischer et al. (1979) was used to estimate the potential long-term buildup of groundwater concentrations and evaluate a range of mixing factors in Todd Creek. The salt balance concept addresses the equilibrium condition in which the salinity advected downstream with current flow in an estuary is equal to the dispersive transport upstream. A similar approach can be used to evaluate the equilibrium condition for transport and mixing of groundwater in Todd Creek. For the purposes of this analysis, the salinity concentration in the salt balance equation is replaced by a concentration of “clean” water, where the clean water is considered to be the water that is available for mixing with the groundwater that seeps into the creek, similar to the way saltwater enters the mouth of an estuary and mixes with the freshwater. The water in Todd Creek is treated as a mixture of clean water that enters through the mouth of the creek and groundwater that seeps in from the project site. Accordingly, the salt balance equation can be rewritten for this scenario as:

$$U_f C K = \left( \frac{\partial C}{\partial x} \right)$$

where:

$U_f$  = the downstream riverine velocity

$C$  = concentration of clean water

$K$  = the longitudinal dispersion coefficient that accounts for all dispersive mechanisms in a tidally influenced creek

$\left( \frac{\partial C}{\partial x} \right)$  = the longitudinal concentration gradient of clean water

This equation says, that under equilibrium conditions, the transport of clean water downstream with currents,  $U_f C$ , is equal to transport upstream due to dispersive mechanisms. This equation can be applied to Todd Creek to describe the distribution of clean water concentrations through the creek and, therefore, the relative concentration of groundwater along the creek.

For the purposes of this analysis, the concentration of clean water,  $C$ , is defined as the relative concentration or fraction of clean water in a sample taken from the creek. Conversely, the relative concentration of the sample that comes from groundwater is  $1-C$  (i.e., a sample of water with no groundwater impact would have a relative concentration of 1.0). For a sample composed of 90 percent freshwater and 10 percent groundwater, the relative concentration,  $C$ , would be 0.9 and the associated concentration, or fraction, of groundwater would be 0.1. Using this approach, the mixing factor for the groundwater can be calculated as  $1/(1-C)$ . For example, if the clean water concentration is 0.9 (90 percent clean water), the relative concentration of groundwater would be 0.1 and the mixing factor would be equal to 10.

If the concentration gradient is taken as the difference in concentration between the site and the mouth of the creek over the distance between the site to the creek mouth and the concentration,  $C$ , is taken as the average concentration along this reach, the concentration of clean water at the site can be calculated as:

$$C_{site} C_0 = \left( \frac{2K - U_f L}{2K + U_f L} \right)$$

where:

$C_{site}$  = concentration of clean water at the site

$C_0$  = concentration of clean water at the mouth of the creek

$L$  = length of the creek segment between the site and the mouth

$U_f$  = downstream riverine velocity

$K$  = longitudinal dispersion coefficient that accounts for all dispersive mechanisms in a tidally influenced creek

In this way, the concentration of clean water at the site can be calculated given the concentration of clean water at the mouth of the creek, the longitudinal dispersion coefficient, and the riverine flow in the creek.

## 2. Estimating the Groundwater Discharge Component

According to the conceptual model approach, the only source of riverine flow is assumed to be the groundwater discharge into Todd Creek from beneath the landfill area. The groundwater flow component was estimated using Darcy's Law to approximate the lateral steady-state flow entering the south side of the creek. This would be the main contributing discharge in the vicinity given the topography in the marshland areas to the north.

Darcy's Law for 1-dimensional steady-state flow toward Todd Creek is defined as follows:

$$Q = T * i * W \Rightarrow K * b * i * W,$$

where:

$Q$  in the discharge ( $L^3/t$ )

$T$  is the aquifer transmissivity ( $L^2/t$ ), or  $K$  (saturated hydraulic conductivity,  $L/t$ ) multiplied by  $b$  (saturated thickness of groundwater zone,  $L$ )

$i$  is the hydraulic gradient of the groundwater flow field (dimensionless)  $W$  is the width of the groundwater flow field along the reach of interest ( $L$ )

Also, by definition:

$V_d$  = the Darcy velocity, ( $L^3/L^2*t$ ) =  $K*i$

$V_s$  = the seepage velocity ( $L/t$ ), calculated as  $V_d$  divided by the effective porosity,  $n_e$ .

So, by substitution,  $Q = V_d * b * W$  becomes the working equation for estimating groundwater flow to Todd Creek. Values for the input variables are defined below:

- $V_s$  has been previously reported (42<sup>nd</sup> Semi-Annual Groundwater Monitoring and Corrective Actions Report [CH2M 2010]) as approximately 98 feet/year, or about 0.27 feet/day, through the area;
- Assuming an  $n_e$  of approximately 0.3 for media results in an estimated  $V_d$  of ~0.081 feet<sup>3</sup>/foot<sup>2</sup>-day (i.e., 0.27 \* 0.3);

- A saturated thickness of 80 feet is a reasonable estimate for the surficial aquifer beneath the area, based on hydrogeologic information for the area;
- The width of the groundwater flow field toward the creek adjacent to the landfill is taken to be the approximate width of the landfill, or about 1,750 feet.

Thus, substituting the parameter values provides an estimated steady-state groundwater flow,  $Q$ , of about 11,340 cubic feet per day ( $\text{ft}^3/\text{day}$ ), rounded up to an estimated  $Q$  of 11,500  $\text{ft}^3/\text{day}$ , or equivalent to 0.13  $\text{ft}^3$  per second.

### 3. Estimating the Mixing Factor Range

For the mixing factor calculations,  $L$  is assumed to be 2.88 miles, the approximate channel distance from the site vicinity to the mouth of Todd Creek at Fairfield Point (Figure 1), and the concentration of clean water at the mouth is set to 1 (i.e., all chemical concentrations in groundwater are effectively removed at this point by the downgradient reaches of Floyd Cut and the Satilla River). As previously noted, the groundwater contribution to Todd Creek in the landfill area was assumed to be the only source of riverine flow. This should be considered a very conservative assumption, since groundwater flow from the site represents only a small fraction of the groundwater entering the creek along its length, and also neglects numerous un-gauged surface water tributaries flowing into Todd Creek.

Site-specific measurements of the longitudinal dispersion coefficient are not available; therefore, a range of values for this application was used based on published values (Fischer et al. 1979) ranging from 10 to 1,500 square meters per second ( $\text{m}^2/\text{s}$ ) (108 to about 16,000 square feet per second [ $\text{ft}^2/\text{s}$ ]), with the bulk in the range of 100 to 300  $\text{m}^2/\text{s}$  (1,080 to 3,240  $\text{ft}^2/\text{s}$ ). It is noted that the lowest values presented, between 10 and 50  $\text{m}^2/\text{s}$  (108 and 540  $\text{ft}^2/\text{s}$ ), are generally found in the constant-density portions of estuaries.

As another conservative assumption, it was assumed Todd Creek was completely mixed with a longitudinal dispersion coefficient range of 10 to 60  $\text{m}^2/\text{s}$  (108 to 646  $\text{ft}^2/\text{s}$ ). The value of  $K = 60 \text{ m}^2/\text{s}$  is a theoretically calculated limit for shear flow dispersion in a constant-density estuary.

As outlined above, the contributing groundwater discharge from beneath the landfill area was set to 0.13 cubic feet per second ( $\text{ft}^3/\text{s}$ ). Transect cross-section data shown on Figures 2 and 3 were used to determine the approximate flow area for the creek. Based on these data, a cross-sectional area of 4,500 square feet was chosen. This selected area represents the smallest value and thus conservatively represents the mixing zone within the cross-section.

The mixing factor is the reciprocal of the relative concentration ( $C$ ). Because the relative groundwater concentration is, by definition ( $1-C$ ), the groundwater mixing factor at the site can be calculated as follows:

$$S_{GW} = \left( \frac{1}{1 - C_{\text{site}}} \right)$$

where:

$S_{GW}$  = the mixing factor for groundwater flow from the site

$C_{\text{site}}$  = relative clean water concentration at the site

To estimate a concentration of a constituent in the creek surface water, the concentration of the constituent in the groundwater is divided by the calculated mixing factor.

## 4. Results and Conclusions

Mixing factors calculated as described above are presented in Table 1:

**TABLE 1. Mixing Factors for Todd Creek**

| Longitudinal Dispersion Coefficient, K |                      | Mixing Factor |
|----------------------------------------|----------------------|---------------|
| (m <sup>2</sup> /s)                    | (ft <sup>2</sup> /s) |               |
| 10                                     | 108                  | 240           |
| 60                                     | 486                  | 1,440         |

The values presented in Table 1 should be considered conservative for the following reasons:

- Mixing was calculated based on longitudinal dispersion coefficients representative of shear flow dispersion in well-mixed estuaries with the water available for mixing entering at the mouth of the creek. Todd Creek overflows its banks onto the tidal marsh to the north daily, resulting in tidal trapping and additional mixing with water from the Satilla River, both of which increase mixing and reduce concentrations of constituents discharging from groundwater into the creek.
- Riverine flow was assumed to be due to groundwater contributions from the site only.
- Additional freshwater flows due to other groundwater seeps along the length of the creek and numerous other freshwater inflows upstream of the site provide additional water and advect the groundwater away more rapidly, resulting in less buildup at the site.
- The smallest cross-sectional area surveyed in Todd Creek was used. This reduces the level of calculated mixing with water from downstream and decreases the calculated mixing factor. Larger river areas downstream of the site result in lower velocities and a greater amount of "clean" water from the mouth to penetrate upstream through dispersive mechanisms and mix with the groundwater at the site.

Based on the conservative analysis described above, the estimated range of mixing factors is from 240 to 1,440. The lower end of this range is believed to be unrealistically low based on factors discussed above. Considering the conservatism built into these calculations, using a mixing factor of 1,440 is more realistic.

This technical memorandum presents risk-based screening levels (SLs) for surface water discharge based on recreational use and fish/crab ingestion scenarios. These SLs are provided to update risk-based standards (CH2M 2011) for surface water discharge from the Union Carbide Corporation (UCC) Woodbine Facility to Todd Creek. The SLs for both recreational use and fish/crab ingestion scenarios were developed for adult and youth receptors.

### 1. Recreational Use Screening Levels for Surface Water

The most realistic recreational activity in the Todd Creek segment adjacent to the landfill site is wading. Swimming is an unrealistic recreational activity for Todd Creek adjacent to the landfill for the following reasons:

- It is located in a rural area primarily composed of agricultural and conservation/preservation land remote from residences and population centers.
- The shoreline conditions consist of steep eroding bluffs or riprap.
- Biological hazards (e.g., alligators, Eastern Cottonmouth snakes, biting insects) are present.
- It lacks public beaches, and the adjoining land use is conservation or industrial with limited access and no areas developed for swimming.

Recreational exposure to surface water during wading includes incidental ingestion and dermal contact pathways. The SLs were developed for adult and youth (6- to 16-year-old) receptors using the U.S. Environmental Protection Agency's (EPA's) Regional Screening Level (RSL) calculator (EPA 2023) based on a target excess lifetime cancer risk of  $1 \times 10^{-6}$  and target hazard quotient (HQ) of 1<sup>1</sup>. The exposure parameter values were based on standard U.S. Environmental Protection Agency (EPA) values (EPA 2004, 2011, 2014a, 2019) and site-specific assumptions based on observations made during the site reconnaissance on September 19, 2023, which included the following:

- Entrance to the property is restricted by a perimeter fence and a locked gate.
- The site is heavily wooded with various wildlife present.
- The Todd Creek segment of interest (near the landfill) is more than 2 miles from the site entrance.

<sup>1</sup> Few chemicals are expected to be present at the groundwater-surface water interface; many oral toxicity values for chemicals on the groundwater analyte list have uncertainty factors  $\geq 1,000$ ; few chemicals on the groundwater analyte list act on same target organ/system.

- The closest access for a trespasser is from the Ceylon Wildlife Management Area and requires driving several miles of unimproved roads to reach Todd Creek near the segment of interest.

The reasonably foreseeable future site use<sup>2</sup> is consistent with the exposure assumptions used. The SLs are summarized in Table 1. The calculations for skin surface area exposed during wading are presented in Table 2. Additional exposure parameter values used in the SL calculations are presented in Attachment A (surface water SLs for adult wading) and Attachment B (surface water SLs for youth wading).

The main exposure parameters used to calculate surface water SLs for the recreational wading scenario are summarized below:

- **Surface water exposure frequency:** 12 events per year (professional judgment; site access is prohibited and secure, and shoreline is remote from populated areas; Todd Creek is not attractive for wading due to shoreline conditions [rip rap, steep banks, mud flats, snakes, alligators, ticks, flies]).
- **Surface water exposure duration:** 20 years (adult) and 10 years (youth) (EPA default for adult resident; assumed 10 years during youth ages; conservative for a wading scenario).
- **Surface water exposure time:** 1 hour per event (professional judgment; Todd Creek shoreline is unattractive due to biological hazards [see above] and site access is prohibited and secure).
- **Surface water incidental ingestion rate:** 0.011 liter per hour (Table 3-96 of *Exposure Factors Handbook, Chapter 3 Update*; wading/splashing upper confidence limit [EPA 2019]).
- **Skin surface area:** 6,456 square centimeters (cm<sup>2</sup>) (adult) and 4,175 cm<sup>2</sup> (youth) (Table 2) (EPA 2004, 2011).

## 2. Fish/Crab Consumption Screening Levels for Surface Water

Surface water SLs based on fish and crab consumption were developed for adult and youth receptors. The surface water SLs were developed by calculating chemical-specific fish/crab consumption SLs using EPA's RSL calculator (EPA 2023) (based on a target excess lifetime cancer risk of  $1 \times 10^{-6}$  and target HQ of 1<sup>3</sup>) and combining the fish/crab consumption SLs with chemical-specific surface water-to-fish/crab bioconcentration factors (BCFs). The exposure parameter values were based on standard EPA values (EPA 2014a) and site-specific assumptions based on observations<sup>4</sup> made during the site reconnaissance on September 19, 2023. The reasonably foreseeable future site use is consistent with the exposure assumptions used. The surface water SLs are summarized in Table 1. The BCFs used in the surface water SL calculations are presented in Table 3. Additional exposure parameter values used in the SL calculations are presented in Attachment C (fish/crab consumption SLs for adults) and Attachment D (fish/crab consumption SLs for youth).

The main exposure parameters used to calculate surface water SLs for the fish/crab consumption scenario are summarized below:

- **Fish/Crab consumption exposure frequency:** 60 days per year (professional judgment; there is limited access to surface water in the Todd Creek segment of interest and both fish and crab are present; fishing/crabbing is assumed to occur from small boats.).

---

<sup>2</sup> UCC plans on placing an Environmental Covenant and conservation easement on the property, the property may be sold to GA DNR for use as a wildlife management area, and accessibility will remain limited (no public access).

<sup>3</sup> Few chemicals are expected to be present at the groundwater-surface water interface; many oral toxicity values for chemicals on the groundwater analyte list have uncertainty factors  $\geq 1,000$ ; few chemicals on the groundwater analyte list act on same target organ/system.

<sup>4</sup> Floats indicating crab traps were observed in the Todd Creek segment of interest.

- **Fish/crab consumption exposure duration:** 20 years (adult) and 10 years (youth) (EPA default for adult resident; assumed 10 years during youth ages).
- **Fish/crab ingestion rate:** 36.3 grams per day (adult) and 17.8 grams per day (youth) (marine finfish & shellfish [90th percentile, 95% confidence interval] for coastal regions [Table 10b and Table 21b of EPA 2014b]; conservative for EPA Region 4<sup>5</sup>).
- **BCFs:** Chemical-specific values obtained from *National Recommended Water Quality Criteria* (EPA 2002) and *Risk Assessment Information System* (RAIS 2023). For polycyclic aromatic hydrocarbons (PAHs), a BCF of 1 was used because PAHs are readily metabolized by fish and are not expected to bioaccumulate in tissue or biomagnify in the food chain (ATSDR 1995).
- **Percentage of fish/crab home range represented by the Todd Creek segment:** 50%. The Todd Creek segment of interest is an intertidal creek with brackish water. A conservative estimate using professional judgment by biologists; recreationally caught fish move around a lot, and their presence/abundance varies seasonally. Blue crabs move up and downstream seasonally and in response to changes in salinity. In addition, crabbers move traps seasonally based on the presence of crabs.

## 2.1 Selection of Screening Levels

On a chemical-specific basis, the lowest of the adult and youth SLs (considering recreational use and fish/crab ingestion scenarios) was identified. Where a Georgia Instream Water Quality Standard was available, it was used as the final surface water screening level rather than a calculated risk-based screening level based on wading or fish/crab consumption. A conservative dilution factor of 1,000 was calculated to account for mixing of groundwater from the landfill area with surface water in Todd Creek (Attachment 3); however, no adjustment was made to the groundwater SLs to account for dilution. In addition, attenuation of constituents of concern in the aquifer between the monitoring wells and the point of discharge to surface water was not accounted for in the development of the SLs. Therefore, these SLs are highly conservative for application to groundwater concentrations at the point of compliance wells. The final surface water SLs are presented in the last column of Table 1.

<sup>5</sup> EPA Region 4 Supplemental Guidance (EPA 2018) mentions use of the fish ingestion rate provided in EPA's *Exposure Factors Handbook* (2011) and *Human Health Ambient Water Quality Criteria: 2015 Update* (EPA 2015). The *Exposure Factors Handbook* (Table 10-3) presents 18 g/day (ages >18 years) and 13 g/day (ages 11 to <16) (95th percentile rates) for recreational marine fish in the Atlantic region. The *Human Health Ambient Water Quality Criteria* presents 22 g/day (90th percentile rate of fish and shellfish from inland and nearshore waters for U.S. adult population 21 years of age and older, based on NHANES data from 2003 to 2010).

| Fluorene              | 86-73-7  | 52,100                                    | 44,100    | 1,072,000                        | 1,202,000         | 5300 (GA ISWQS)               |
| Phenanthrene [e]      | 85-01-8  | 280,000                                   | 238,000   | 8,040,000                        | 9,020,000         | 238,000                       |

Notes:

- a. RSL calculator input and outputs for adult recreator are presented in Attachment A.
- b. RSL calculator input and outputs for youth recreator are presented in Attachment B.
- c. RSL calculator input and outputs for adult fish ingestion SLs are presented in Attachment C.
- d. RSL calculator input and outputs for youth fish ingestion SLs are presented in Attachment D.
- e. Surrogates: anthracene for phenanthrene, nickel soluble salts for nickel.
- f. Surface water SLs based on fish ingestion were calculated using RSL calculator outputs (Attachments C and D) and BCF (Table 3) per following equation:  

$$\text{Surface Water SL } (\mu\text{g/L-sw}) = \text{Fish SL (mg/kg-fish)} \times 1000 (\mu\text{g/mg}) / \text{BCF (L-sw/kg-fish)} / 50\%.$$
- g. Risk-based screening levels are based on target risk of  $1 \times 10^{-6}$  and target hazard quotient of 1.
- h. There is no recreational SL for acetonitrile or sulfide due to lack of ingestion and dermal toxicity values.
- i. The SLs based on fish and crab ingestion are based on the Todd Creek segment being 50% of the fish/crab home range.
- j. The GA ISWQS was selected as the SL for those constituents with a GA ISWQS.
- k. The lowest costal/estuarine GA ISWQS was used for the SL where multiple GA ISWQS were available.

BCF = bioconcentration factor

GA ISWQS = Georgia instream water quality standard

mg/kg = milligram per kilogram

NTX = a toxicity value is not available

RSL = regional screening level

SL = screening level

sw = surface water

µg/L = microgram per liter

µg/mg = microgram per milligram

Notes:

<sup>1</sup> Skin surface area - Table 7-2 of Exposure Factors Handbook (EPA, 2011)<sup>2</sup> Adjustments for face to head, forearm to arm, and lower leg to leg - Exhibit C-1 of RAGS Part E (EPA, 2004).

Face SA was assumed to be 1/3 of head SA.

Forearm-to-arm ratio was assumed to be 0.45.

Lower legs-to-leg ratio was assumed to be 0.4.

SA - surface area

Table 3. Bioconcentration Factors for Surface Water to Fish  
Appendix G - Human Health Risk Assessment  
UCC Woodbine, Camden County, Georgia

Notes:

[a] PAHs are readily metabolized by fish and are not expected to bioaccumulate in tissue or biomagnify in the food chain (ATSDR, 1995).

Therefore, a BCF of 1 was used for PAHs.

[b] If a BCF was not available, a default value of 1 was used.
