---

A screening-level ecological risk assessment (SLERA) (Steps 1 and 2) and the Step 3a of the Baseline Ecological Risk Assessment (BERA) were performed for the landfill at the Union Carbide Corporation Woodbine facility (site). The SLERA and Step 3a evaluate risks to aquatic receptors from groundwater that may discharge to Todd Creek. The SLERA and Step 3a were performed in accordance with the following guidance:

- *Ecological Risk Assessment Guidance for Superfund (RAGS): Process for Designing and Conducting Ecological Risk Assessments* (EPA 1997)
- *Region 4 Ecological Risk Assessment Bulletins – Supplement to RAGS* (EPA 2001)
- *Evaluating Ground-Water/Surface-Water Transition Zones in Ecological Risk Assessments* (EPA 2008a).

## 1. Screening-Level Problem Formulation

The SLERA is conducted using intentionally conservative assumptions to identify chemicals of potential ecological concern (COPECs). The principal components of the SLERA are problem formulation (Step 1), exposure estimation, effects evaluation, and risk calculation (Step 2). Problem formulation establishes the goals, scope, and focus of the SLERA. A description of the site setting and summary of available data is compiled to formulate the conceptual site model (CSM). From this information, the exposure pathways, target receptors, and potential effects are determined and serve as the focus for Step 2.

### 1.1 Site Description and Background

The site is located in the Coastal Plain Marine Flatlands region of the Atlantic Coastal Plain physiographic province. The site is within two subregions, the Coastal Marine Flatlands and the Tidal Marine Area. Groundwater from the site in both shallow and deep zones flows to Todd Creek located to the north. More than half of the site is tidal marsh associated with the Satilla River and Todd Creek. The remainder of the site includes scattered wetlands and uplands. The landfill area is currently fenced and has a maintained clay cap cover with grasses and ruderal weeds.

### 1.2 Aquatic Habitat and Receptors

The Satilla River, a tidal river, flows along the northern boundary of the site. Todd Creek, which parallels the Satilla River and includes Floyd Basin, is a tidal creek. These two streams are connected hydrologically through an extensive tidal marsh. Wharton (1978) classified this type of habitat as a coastal marine marsh tidal system. In the western portion of the property, near the former Rocket Test Pit, the banks of Todd Creek are undergoing severe erosion and have undercut banks approximately 15 ft above the stream.

Tidal rivers and creeks support a diverse invertebrate faunal assemblage, with studies indicating up to 20 species of amphipods, 16 species of nantid shrimp, 14 polychaete worm species, 16 crab species, 9 bivalve mollusks, and 9 gastropod mollusks (Wharton 1978). Macrophytic vegetation typically is lacking from the channels of tidal rivers and creeks. Fish species vary with salinity, with higher salinity tending to result in greater numbers but fewer species of fish (Wharton 1978).

Vegetation within the tidal marsh is dominated by near monoculture stands of cordgrass (*Spartina* spp.), saltgrass (*Distichlys spicata*), and black rush (*Juncus roemerianus*). These plants segregate into distinct zones, with cordgrass occurring mostly seaward and black rush occurring mostly inland. The zones divide along salinity gradients. Common animals include numerous species of frogs and snakes, alligators, garfish, and bowfin. Shorebirds and ducks frequent the salt marsh, with particularly high numbers found during winter. Osprey and bald eagles are common, with both species observed nesting on or adjacent to the site. Marsh rabbits and rice rats typically are the most abundant mammals.

The remainder of the site includes scattered wetlands and uplands.

### 1.3 Protected Species

A site survey conducted on July 12, 2004, indicated that the state and federally threatened American alligator (*Alligator mississippiensis*), state and federally endangered wood stork (*Mycteria americana*), state-threatened bald eagle (*Haliaeetus leucocephalus*), and state-threatened gopher tortoise (*G. polyphemus*) occur on the site. The state and federally threatened eastern indigo snake (*D. corais couperi*) also is known to occur on the site, though it was not seen during the site survey. In November 2023, the Georgia Department of Natural Resources Biodiversity Portal was queried to verify the current status of these species. As of this time there has been no change in status. There have been no changes to the site since 2004 that would affect the types of species likely to be present. The site remains undeveloped with the exception of the landfill which is regularly mowed.

The American alligator was observed in the deep part of the borrow pit used for excavation of the material used for the landfill cap. Juvenile wood storks were observed foraging in the wet weather pond near the southern boundary of the property. This species also could forage along the edge of the borrow pit by the landfill or along mudflats and shallows along Todd Creek. There is a known bald eagle nest on the land adjacent to the property to the west. Two adult eagles and one juvenile eagle were observed soaring above the abandoned airstrip and the wetlands on the southwestern part of the property. This species could forage along Todd Creek and Floyd Basin and in the borrow pit adjacent to the landfill. Gopher tortoises are found throughout the property between the airstrip and Todd Creek and also on the peninsula where the Floyd Family cemetery is located. The indigo snake could occur throughout the areas where gopher tortoise are found.

The tidal marsh along Todd Creek and the Satilla River on the northern portion of the property provides habitat that may be used by piping plover (*Charadrius melodus*) and gull-billed tern (*Sterna nilotica*) and periodically used by the peregrine falcon (*Falco peregrinus*) during migration. No potentially suitable nesting or roosting habitat was identified for the swallow-tailed kite (*Elanoides forficatus*), but this species could forage over the property. The Florida manatee (*Trichechus manatus*) may occasionally enter the channels of Todd Creek and the Satilla River.

Potentially suitable habitat has been identified for the state-threatened climbing buckthorn (*Sageretia minutiflora*) and the state-threatened narrowleaf obedient plant (*Physostegia leptophylla*) in the tidal marsh areas.

## 1.4 Conceptual Site Model

The CSM is presented in Figure 1 and key components of the CSM are discussed in Section E.9d of the Post-Closure Care and Corrective Action Permit HW 063(D) Application Renewal Application. Potential migration pathways and media of concern at the site are primarily leaching of subsurface wastes to shallow groundwater, and the hydraulic connection between shallow and deeper water-bearing zones within the uppermost aquifer. The groundwater in both shallow and deep zones flows to Todd Creek located to the north.

As noted above, in Todd Creek, there are potentially complete exposure pathways for aquatic plants and animals exposed to chemicals in surface water, chemicals that may partition to sediment, and chemicals in the transition zone from groundwater to surface water. Plants and animals may be exposed to chemicals via direct (dermal) contact with constituents in water, sediment, and transition zone water. Animals may be exposed to chemicals through one or more of the following pathways:

- Incidental ingestion of constituents in sediment during feeding or preening activities;
- Direct ingestion of constituents in water;
- Ingestion of constituents in plant and/or animal tissues (for chemicals that have entered food webs);
- Dermal contact with constituents in sediment, surface water, or transition water. Dermal exposure is expected to be small for receptors with hair or feathers. However, dermal contact may be a significant pathway for receptors that live in or on sediments (e.g., worms and crabs) or have gills (e.g., fish and shrimp).

Exposure pathways from groundwater to remaining areas of the site, including the scattered wetlands and uplands, are incomplete. Since the landfill is covered with a clay cap, pathways to terrestrial biota in contact with the landfill are also incomplete.

## 1.5 Assessment and Measurement Endpoints

The assessment endpoints for this site are adverse effects to aquatic plant and animal communities in surface water, sediment, and the groundwater-surface water transition zone. The measurement endpoint evaluations for this site are the effects of chemical exposure on reproduction, survival, or growth, which can be used to predict effects at all levels of organization (individual, population, and community); these were considered in the identification and evaluation of the appropriate toxicity information.

## 1.6 Summary of Available Analytical Data

The primary medium of interest for the landfill is groundwater that may discharge to the adjacent area of Todd Creek. For the SLERA, groundwater data collected from 2017 to 2023 in the point of compliance wells (MW-6, MW-7, MW-8, MW-34, MW-38, MW-39) and point of exposure wells (MW-17, MW-18, MW-20, MW-21, MW-23, MW-24, MW-25, MW-41, MW-42) were used (Attachment 1). Only constituents with reported detections were evaluated (Tables 1 and 2).

## 2. Screening-Level Effects Evaluation

The purpose of the screening-level effects evaluation is to establish chemical exposure levels (screening values) that represent conservative thresholds for adverse ecological effects. Based on the CSM, exposures to surface water and sediment through the groundwater/surface water transition, resulting from groundwater discharge, are complete pathways.

Potential effects from groundwater discharge were evaluated by screening groundwater concentrations with surface water screening values. This approach is consistent with EPA (2008a) and expected to be protective of exposures associated with sediment, pore water, and surface water, for the following reasons:

- Groundwater is treated as the exposure medium with no dilution or partitioning between exposure media.
- Screening values based on National Recommended Water Quality Criteria are considered protective of benthic invertebrates.
- Because of the high solubility and low adsorption of most of the dissolved chemicals in site groundwater, they have a low bioaccumulation potential and are not expected to be adsorbed to the organic carbon in sediment.

EPA Region 4 saltwater values were selected for the screening. When no saltwater value was available, the Region 4 freshwater value was used. Region 4 screening values are intended to be protective of all aquatic receptors and exposure pathways and were therefore considered appropriate for the assessment endpoints in this evaluation.

### **3. Screening-Level Exposure Estimation**

Consistent with the conservative nature of the SLERA and the iterative approach to evaluating groundwater discharge, maximum groundwater concentrations were used in the SLERA.

### **4. Step 2 Screening-Level Risk Calculation**

The screening-level risk calculation is the final step in the SLERA. In this step, the maximum detected groundwater concentrations are compared with the corresponding screening values to derive screening risk estimates.

COPECs are selected using the Hazard Quotient (HQ) method. HQs are calculated by dividing the maximum detected concentration by the corresponding screening value. Chemicals with HQs greater than or equal to 1.0 are considered COPECs in the SLERA. Detected chemicals for which toxicological data were not available also were identified as COPECs in the SLERA.

#### **4.1 Selection of Chemicals of Potential Ecological Concern**

The maximum groundwater concentrations are compared to the screening values in Table 2. Of the 32 detected chemicals, 10 had maximum concentrations that exceeded the screening value (i.e., had an HQ greater than or equal to 1.0), and 4 or had no screening value; therefore, 14 COPECs were identified.

### **5. Scientific Management Decision Point 1**

Upon the completion of the SLERA, COPECs were identified for groundwater. This stage of the process represents a Scientific Management Decision Point. Because one or more COPECs were identified during the screening process, additional evaluation in the Step 3a BERA was conducted for this site.

### **6. Step 3a Baseline Ecological Risk Assessment**

According to Superfund guidance (EPA 1997), Step 3 initiates the problem formulation phase of the BERA. In the initial step of the BERA, the COPECs from the SLERA are reexamined using more realistic exposure assumptions to determine the range of potential risks and to determine whether the COPECs

should be eliminated from further consideration. In this initial refinement of the COPECs, the conservative assumptions used in the SLERA are refined, and risk estimates are recalculated.

The assumptions modified for the refinement included the following:

- The maximum detected concentration was replaced with the 95% Upper Confidence Limit on the mean (95UCL). EPA (2008a) recommends “using more realistic exposure point concentrations than those evaluated in the screening [ecological risk assessment] ERA.” These new comparisons will not use maximum detected groundwater concentrations as in the screening ERA, but rather use exposure point concentrations that are reasonably anticipated or expected to exist or occur at a site (the reasonable maximum exposure).” The 95UCL using ProUCL 5.1 was calculated and the ProUCL recommended value was used as the reasonable maximum exposure concentration. ProUCL outputs are included in Attachment 2.

The results of the comparison of the refined exposure concentrations (95UCL, mean value when no UCL could be calculated, or mean detection limit for nondetected chemicals) to screening values (including Oak Ridge National Laboratory and surrogate screening values) are presented in Table 2. Only two COPECs, trichlorophenoxyacetic acid and Barium, had a 95UCL that exceeded the screening value. No other chemicals had exposure concentrations greater than the screening values. Risks from constituents with concentrations below screening values are considered negligible and no further assessment is necessary.

In the case of trichlorophenoxyacetic acid only one result, the maximum (140 micrograms per liter [µg/L]) exceeded the saltwater screening value of 50 µg/L. The other detections ranged from 0.27 to 46 µg/L.

Barium concentrations ranged from 3.9 to 90.6 µg/L, so all but one sample exceeded the screening criteria of 4 µg/L. As previously noted, the screening values are selected to be conservative and error on the side of over protection. If the same results are screened against the Region 4 recommended freshwater value of 220 µg/L no results exceed.

## 7. Uncertainty Assessment

Uncertainties are present in all risk assessments because of the limited available data and the need to make assumptions and extrapolations based on incomplete information. The key uncertainties associated with the calculation of risk in this ERA are listed below:

- Consistent with the approach in EPA (2008b), the maximum or reasonable maximum exposure concentration in groundwater was used for comparison to surface water screening values. However, the concentrations in the groundwater/surface water transition zone and surface water are expected to be diluted significantly from those measured in groundwater. A conservative mixing factor of 1,000 for groundwater to surface water has been presented (Attachment 3), based on the hydrological characteristics of the creek. Since mixing in the groundwater/surface water transition zone was not estimated and is assumed to be less than 1,000 in localized areas, no mixing factor was applied to the groundwater concentrations, when evaluating exposure point concentrations to transition zone biota, which is expected to result in an overestimate of risks.
- Only the most recent data (2017-2023) were used to calculate the 95UCL.
- Risk for some analytes could not be estimated because screening values were lacking. This includes, aldicarb, pyridine, sulfate, and reactive sulfide.
- Information on the ecotoxicological effects of chemical interactions is generally lacking, which required (as is standard for ERAs) that some chemicals (particularly inorganic constituents) be evaluated on a compound-by-compound basis during the comparison to screening values. This could

result in an underestimation of risk (if there are additive or synergistic effects among chemicals) or an overestimation of risks (if there are antagonistic effects among chemicals).

## **8. Scientific Management Decision Point 2**

At Scientific Management Decision Point 2, the results of the BERA problem formulation are considered by the risk managers in determining whether they concur with the assessment endpoints, representative receptors, exposure pathways evaluated, and the conclusions regarding the final COPECs. In this ERA, risks from COPECs are considered negligible and no further assessment is recommended.

Groundwater from the site in both shallow and deep zones flows to Todd Creek. In Todd Creek, there are complete exposure pathways for aquatic plants and animals exposed to chemicals in groundwater discharged to surface water, in sediment, and in the transition zone from groundwater to surface water. In the SLERA, maximum groundwater concentrations were compared to surface water screening values. Of the 32 detected chemicals, 14 were identified as COPECs because the concentrations exceeded the Region 4 benchmarks (10) or had no screening value (4). Because one or more COPECs were identified during the screening process, additional evaluation in the Step 3a BERA was recommended.

In the Step 3a BERA, the COPECs from the SLERA were reexamined using more realistic exposure assumptions to determine the range of potential risks and to determine whether the COPECs should be eliminated from further consideration. As indicated above, the conclusion of the analysis was that risks to populations of creek receptors associated with exposure to groundwater-related constituents are unlikely to be significant. This conclusion is considered to be conservative because (1) dilution upon discharge was not taken into account, (2) the sample-specific concentration for a nondetected constituent was assumed to be equivalent to the detection limit (except in cases where there were too many nondetects to calculate a 95UCL), and (3) the groundwater concentrations detected at each location may not accurately represent the concentration likely to discharge to the creek (sample turbidity could have been elevated in some cases and attenuation/degradation would be likely to occur during migration toward the creek). Considering the 1,000-fold dilution factor (Attachment 3) only, estimated surface water exposure concentrations would be reduced by three orders of magnitude in the creek in a short time period after discharge.

Notes:

Shaded cells indicate HQ >1

µg/L = micrograms per liter

< = less than

% = percent

Eco = ecological

HQ = hazard quotient

MDL = method detection limit

MW = monitoring well

NSV = no screening value available

QL = quantitation limit

RL = reporting limit

UCC = Union Carbide Corporation

UCL = upper confidence level

**Figure**

**FIGURE 1**  
Conceptual Site Model for UCC Woodbine Site  
Human and Ecological Receptors  
*Appendix G - Ecological Risk Assessment*  
UCC Woodbine, Camden County, Georgia

NC = Pathway is incomplete  
NA = Not Applicable  
X = Completed exposure pathways  
<sup>1</sup> = Assumes no dilution attenuation as groundwater releases to surface water bodies. Fish ingestion pathway was evaluated.  
<sup>2</sup> = EPA Region 4 Supplemental Guidance to RAGS (2008) states "in most cases it is unnecessary to evaluate human exposures to sediments covered by surface water."  
<sup>3</sup> = Groundwater from POC/POE wells was evaluated for potential discharge to the creek in this risk assessment.  
<sup>4</sup> = Sediment exposure pathway is not considered significant due to low partitioning of most of the groundwater constituents to sediments.  
- - - ➔ = Dashed arrow indicates potentially incomplete or insignificant exposure pathway (see above Note 4)
